## **Abstract**

La tesi si propone di analizzare la risolubilità di equazioni differenziali alle derivate parziali di tipo ondulatorio e le loro proprietà tramite la costruzione di soluzioni fondamentali distribuzionali. Dapprima si affronterà il caso nello spazio di Minkowski  $n$ -dimensionale e poi si trasporteranno, per quanto possibile, le principali proprietà delle soluzioni su particolari varietà curve di interesse per le loro applicazioni fisiche.

The aim of the thesis is to analyse the solvability of wave-like partial differential equations and their properties via the construction of distributional fundamental solutions. Initially will be explored the  $n$ -dimensional Minkowski case and then the main properties of the solutions will be translated, when possible, on particular manifolds, interesting for their physical applications.

# Introduction

---

Wave-like equations are a class of differential equations which rule the dynamics of many physical processes, from electromagnetism to quantum field theory. Such equations contain a differential operator  $P$ , which is a generalization of the d'Alembert wave operator

$$\square := \frac{\partial^2}{\partial t^2} - \sum_{j=1}^{n-1} \frac{\partial^2}{\partial x_j^2},$$

that describes the propagation of a wave with velocity  $c \equiv 1$  in an  $n$ -dimensional spacetime. In this thesis will be presented a constructive method of fundamental solutions to solve wave-like differential equations, firstly on a flat background and then on suitable manifolds of physical interest, where the standard methods used in the Minkowskian scenario are not applicable.

Fundamental solutions are used to solve inhomogeneous equations of the form  $Pf = \psi$ , where  $\psi$  is a generic source. They can be thought as the distributional solutions to a differential equation in which the source is a point-like instantaneous perturbation, namely the Dirac delta. To be more precise, if  $P$  is a differential operator, a fundamental solution  $u_x$  for  $P$  at  $x$  is a distributional solution to the equation

$$Pu_x = \delta_x.$$

Once a fundamental solution  $u_x$  is found, it is easy to find the desired solution  $f$  of the equation  $Pf = \psi$  and deduce the properties of the solution.

In a flat spacetime, when dealing with wave operator  $\square$ , it turns out that the fundamental solutions can be constructed by applying the methods of the Fourier transform to the underlying partial differential equation. Moreover, the translational symmetry of the background allows the solution for  $Pf = \psi$  to be given simply by the convolution  $u_0 * \psi$ , namely it suffices to solve the problem at any but fixed point of the background, which can thus be chosen without loss of generality to be. In particular we will describe two fundamental solutions at 0, denoted with  $G_+$  and  $G_-$ , the *retarded* and the *advanced* one, that propagate the source of the equation respectively in the causal future and in the causal past, in accordance with the causality principle.

When dealing with wave-like operators on generic Lorentzian manifolds, there is no symmetry available. Hence, in order to find fundamental solutions it is necessary to follow another path. In Chapter 2, following the construction of [2] and [5], we define on Minkowski spacetime a family of distributions, dubbed *Riesz distributions*  $R_{\pm}(\alpha)$ , supported respectively on the future and on the past of 0, depending on a complex parameter  $\alpha$ , when  $\text{Re } \alpha > n$ . Subsequently through analytic continuation the family  $R_{\pm}(\alpha)$  is extended to the whole complex plane and some important properties are deduced. It is noteworthy that for the specific value of  $\alpha = 2$ , one finds the aforementioned advanced and retarded fundamental solutions. In addition their support properties can be inferred for any dimension of the underlying flat background, hence proving the so-called *Huygens' principle* (see Section 2.4 and Theorem 2.5.9).

Within the framework of flat space, we will address the Cauchy problem for  $\square f = \psi$ , with initial data to be set on a particular class of hypersurfaces: Cauchy hypersurfaces (see Definition 1.2.22). These surfaces are strongly related to the causality principle. In fact any point of a Cauchy hypersurface is not in the past nor in the future of any other point of the surface, i.e. the initial data cannot influence each other. In view of these considerations, the existence and uniqueness of the solution will be shown.

Then we will focus on the problem of analyzing the solutions of wave-like operators on a suitable class of Lorentzian manifolds. We give examples of such operators on backgrounds of physical interest, such as the cosmological and the Schwarzschild spacetimes. Then we will try to use Riesz distributions, which are well-suited for generalization, to solve the problem locally. To tackle this problem our strategy is the following: At any but fixed point  $x \in M$  we can consider the tangent space and a coordinate system such that the metric reads as the Minkowski one at  $x$ . On  $T_x M$  one can define the Riesz distributions as in the flat scenario. Via the exponential map these can be pulled-back to a local neighbourhood of  $x \in M$ . While this operations preserves most of the

desired properties, it fails to yield fundamental solutions for the operator of interest, neither locally. However, if one combines in a proper manner certain Riesz distributions to form a formal series, one can find local approximate fundamental solutions for a generic wave-like operator that converge to the true one in a suitable way.

The Cauchy problem will be addressed locally, proving that the local solution exists and it is unique, while the support properties, that we found in the flat case, survive on generic manifolds. To find global solutions, we will have to restrict to a particular class of manifolds, the *globally hyperbolic* spacetimes, in order to ensure the existence of a Cauchy hypersurface (see Theorem 1.2.23) where to set initial data.

A synopsis of the thesis is the following:

In the first chapter, it will be presented an overview of the main mathematical notions needed in order to set the discussion on a curved background. The main topics will be *differentiable manifolds*, *tangent space*, *Lorentzian manifolds*, *causality and global hyperbolicity*, *hyperbolic differential operators* as well as the *theory of integration* on manifolds.

In the second chapter, it will be discussed the concept of fundamental solutions and we will focus on the particular case of the d'Alembert wave operator in Minkowski spacetime. Two approaches will be followed: the first relies on the theory of Fourier transform while the second is based on the identification of a particular class of distributions, the *Riesz distributions*, that allow to construct the sought fundamental solutions for any spacetime dimension. At last, an overview of the Cauchy problem for the wave operator will be discussed in the simplest cases.

In the third chapter, we will give some examples of Lorentzian manifolds of physical interest, whose associated, metric induced, wave-like operator is such that the associated fundamental solutions cannot be constructed with the same methods used in Minkowski spacetime. To avoid this hurdle, the first step will be to extend of Riesz distributions to Lorentzian manifolds to be able to identify fundamental solutions of a wave-like operator, first locally and then globally provided that the underlying manifolds abides to suitable, physically and structurally motivated constraints. The Cauchy problem will

be solved both in a local and a global setting, and it will give information on the regularity as well as on the support of the solutions.

## 1.1 An overview of Differential Geometry

We begin by recalling of very well known definitions in order to introduce the basic geometrical objects which are used in the text. In this section we will follow [1] and [2, Ch. A.3]

A **manifold** is, heuristically speaking, a space that is locally similar to  $\mathbb{R}^n$ . To define it we use the concepts of **topological space** and of **homeomorphism**.

**1.1.1 Definition (Topological Space).** *A set  $X$  together with a family  $\mathcal{T}$  (**topology**) of subsets of  $X$  is called a **topological space** if the following conditions are met:*

- a.  $\emptyset, X \in \mathcal{T}$ ,
- b. for all  $U$  and  $V \in \mathcal{T}$ ,  $U \cap V \in \mathcal{T}$ ,
- c. for any index set  $A$ , if  $U_i \in \mathcal{T}$  for all  $i \in A$ ,  $\bigcup_{i \in A} U_i \in \mathcal{T}$ .

An element of  $\mathcal{T}$  is called **open set**. If a point  $p$  is in an open set  $U$ , we call  $U$  a **neighborhood** of  $p$ .

**1.1.2 Definition (Continuity and homomorphism).** *Let  $X$  and  $Y$  be two topological spaces. A function  $f : X \rightarrow Y$  is **continuous** if for any open set  $U$  of  $Y$ , the preimage  $f^{-1}(U)$  is an open set of  $X$ .*

A continuous and bijective map  $\varphi : X \rightarrow Y$  is an **homomorphism** if  $\varphi^{-1} : Y \rightarrow X$  is also continuous.

As for vector spaces, we can talk of a **basis** for topological space. A subset  $\mathcal{B} \subset \mathcal{T}$  is a basis if any open set can be expressed as union of elements of  $\mathcal{B}$ . A topology is **Hausdorff** if, for any two distinct points  $p, q \in X$ , there exist two open neighborhoods  $U$  of  $p$  and  $V$  of  $q$  such that  $U \cap V = \emptyset$ .

A topological space  $X$  is called **compact** if each of its open covers has a finite subcover, i.e. for any collection  $\{U_i\}_{i \in A}$ , (where  $A$  is a set of indexes) such that

$$X \subseteq \bigcup_{i \in A} U_i,$$

there is a finite subset  $A'$  of  $A$  such that

$$X \subseteq \bigcup_{i \in A'} U_i.$$

The closure  $\overline{\Omega}$  of a subset  $\Omega \subset X$  is the smallest closed set that contains  $\Omega$ . We say  $\Omega$  is **relatively compact** if its closure  $\overline{\Omega}$  is a compact subset.

We are now ready to introduce the concept of **manifold**.

**1.1.3 Definition.** An  $n$ -dimensional topological **manifold**  $M$  is a topological Hausdorff space (with a countable basis) that is locally homeomorphic to  $\mathbb{R}^n$ , i.e. for every  $p \in M$  there exists an open neighbourhood  $U$  of  $p$  and a homeomorphism

$$\varphi : U \rightarrow \varphi(U),$$

such that  $\varphi(U)$  is an open subset of  $\mathbb{R}^n$ .

Such homeomorphism is called a **(local) chart** of  $M$ . An **atlas** of  $M$  is a family  $\{U_i, \varphi_i\}_{i \in A}$  of local charts together with an open covering of  $M$ , i.e.  $\bigcup_{i \in A} U_i = M$ .

**1.1.4 Definition.** A **differentiable atlas** of a manifold  $M$  is an atlas  $\{U_i, \varphi_i\}_{i \in A}$  such that the functions

$$\varphi_{ij} := \varphi_i \circ \varphi_j^{-1} : \varphi_j(U_i \cap U_j) \rightarrow \varphi_i(U_i \cap U_j),$$

are differentiable (of class  $C^\infty$ ) for any  $i, j \in A$  such that  $U_i \cap U_j \neq \emptyset$ . Each  $\varphi_{ij}$  is called **transition function**.

 FIGURE 1.1: A differentiable atlas on a manifold  $M$ .

With this definition, each  $\varphi_{ij}$  is a **diffeomorphism** because one can always interchange the indexes  $i$  and  $j$ .

We are only interested in **differentiable** (or **smooth**) **manifolds**, endowed with a maximal differentiable atlas. Here maximality of the atlas means that, if  $\varphi$  is a chart of  $M$  and  $\{U_i, \varphi_i\}_{i \in A}$  is a differentiable atlas, then  $\varphi$  belongs to  $\{U_i, \varphi_i\}_{i \in A}$ . We call a differentiable manifold with an atlas for which all chart transitions have positive Jacobian determinant an **orientable manifold**.

**1.1.5 Remark.** For now on, the word **manifold** will always mean **differentiable manifold** and to indicate them it will be used the letters  $M$  or  $N$ .

**1.1.6 Definition (Submanifold).** Let  $n \leq m$ . An  $n$ -dimensional **submanifold**  $N$  of  $M$  is a nonempty subset  $N$  of  $M$  such that, for every point  $q \in N$ , there exists a local chart  $\{U, \varphi\}$  of  $M$  about  $q$  such that

$$\varphi(U \cap N) = \varphi(U) \cap (\mathbb{R}^n \times \{0\}) \subset \mathbb{R}^m.$$

If  $n = m - 1$  we call  $N$  an **hypersurface** of  $M$ .

**1.1.7 Example.** If  $M$  and  $N$  are manifolds, the Cartesian product  $M \times N$  is endowable with canonical structure of a manifold. If  $\{U_i, \varphi_i\}_{i \in A}$  is an differentiable atlas for  $M$  and  $\{V_j, \psi_j\}_{j \in B}$  is an atlas for  $N$ , then  $\{U_i \times V_j, (\varphi_i, \psi_j)\}_{(i,j) \in A \times B}$  is a differentiable atlas for  $M \times N$ .

As in the Euclidean case, one can introduce the notion of **differentiable** map between manifolds:

FIGURE 1.2: The notion of differentiable map  $f$  between manifolds  $M$  and  $N$ .

**1.1.8 Definition.** A continuous map  $f : M \rightarrow N$  between two manifolds  $M$  and  $N$  is **differentiable** at  $p \in M$  if there exist local charts  $\{U, \varphi\}$  and  $\{V, \psi\}$  about  $p$  in  $M$  and about  $f(p)$  in  $N$  respectively, such that  $f(U) \subset V$  and

$$\psi \circ f \circ \varphi^{-1} : \varphi(U) \rightarrow \psi(V),$$

is differentiable (of class  $C^\infty$ ) at  $\varphi(p)$ . The function  $f$  is said to be differentiable on  $M$  if it is differentiable at every point of  $M$ .

The space of differentiable functions between two manifolds is denoted by  $C^\infty(M, N)$ , and if  $N = \mathbb{C}$  simply by  $C^\infty(M)$ . If  $\psi \circ f \circ \varphi^{-1}$  is of class  $C^k$ , we say  $f \in C^k(M, N)$ .

We introduce the **tangent space** of a point of a manifold. It will be constructed using the derivatives of curves which pass through the point. A tangent vector at a point  $p$  is thought of as the velocity of a curve passing through the point. We can therefore define a tangent vector as an equivalence class of curves passing through  $p$  while being tangent to each other at  $p$ .

**1.1.9 Definition (Tangent space).** Let  $p \in M$  and let  $I$  be an interval containing 0. We indicate  $\mathcal{C}_p = \{c \in C^\infty(I, M) \mid c(0) = p\}$  the set of differentiable curves passing through  $p$ .

We consider the equivalence relation  $(\sim)$ , according to which two curves  $c_1, c_2 \in \mathcal{C}_p$  are equivalent if there exists a local chart  $\varphi$  about  $p$  such that

$$(\varphi \circ c_1)'(0) = (\varphi \circ c_2)'(0).$$

The **tangent space** of  $M$  at  $p$  is the set  $T_p M := \mathcal{C}_p / \sim$ .

We will refer at the equivalence class of curves with  $\dot{c}$ , as they are uniquely determined by the velocity  $(\varphi \circ c)'(0)$  at which they pass through the point  $p$ . One can check that the definition of the equivalence relation does not depend on the choice of local chart. In fact, if  $\{U, \varphi\}$  and  $\{V, \psi\}$  are local charts at  $p$ ,

$$(\varphi \circ c)'(0) = (\varphi \circ \psi^{-1} \circ \psi \circ c)'(0) = D(\varphi \circ \psi^{-1})(\psi(p)) \cdot (\psi \circ c)'(0),$$

where  $D(\varphi \circ \psi^{-1})(\psi(p))$  stands for the Jacobian of the transition function calculated at  $\psi(p)$ . It holds that  $(\varphi \circ c_1)'(0)$  and  $(\varphi \circ c_2)'(0)$  coincide if and only if  $(\psi \circ c_1)'(0)$  and  $(\psi \circ c_2)'(0)$  coincide.

FIGURE 1.3: Tangent space  $T_p M$  where  $c_1 \approx c_2$ .

It can be proven that (for a fixed atlas  $\varphi$  about  $p$ ) the following map is a linear isomorphism between  $T_p M$  and  $\mathbb{R}^n$ :

$$\begin{aligned} \Theta_\varphi : T_p M &\rightarrow \mathbb{R}^n, \\ \dot{c} &\mapsto (\varphi \circ c)'(0). \end{aligned}$$

Hence we can think of  $T_p M$  as being a copy of  $\mathbb{R}^n$  attached to the point  $p$  on the manifold.

For reasons that we will make clear later, we denote the basis of  $T_p M$  as

$$\left\{ \frac{\partial}{\partial x^1} \Big|_p, \dots, \frac{\partial}{\partial x^n} \Big|_p \right\}.$$

Collecting all tangent spaces, one builds the **tangent bundle** of a manifold  $M$ , defined as:

$$TM = \bigsqcup_{p \in M} T_p M = \bigcup_{p \in M} \{p\} \times T_p M.$$

**1.1.10 Definition.** Let  $f : M \rightarrow N$  be a differentiable map and let  $p \in M$ . The **differential** of  $f$  at  $p$  is the linear map

$$d_p f : T_p M \rightarrow T_{f(p)} N, \quad \dot{c} \mapsto [f \circ c] \cong (f \circ c)'(0).$$

The **differential** of  $f$  is the map  $df : TM \rightarrow TN$  such that  $df|_{T_p M} = d_p f$ .

FIGURE 1.4: A scheme of a differential map.

Given  $M$  and a chart  $\{U, \varphi\}$  near  $p$ , fix  $X = \dot{c} \in T_p M$ . If we identify  $T_p \mathbb{R} \cong \mathbb{R}$ , we can interpret the differential  $d_p f(X)$  of a function  $f \in C^\infty(M)$  at a point  $p$  as the **derivative** in the direction of  $X$ :

$$\partial_X f(p) := d_p f(X).$$

A functional which is linear and follows Leibniz rule, such as  $\partial_X : C^\infty(M) \rightarrow \mathbb{R}$ , is called a **derivation**. The set of all derivations at  $p$  is denoted as  $\text{Der}_p$  and it is a vector space. The map  $X \in T_p M \mapsto \partial_X$  is an isomorphism between  $T_p M$  and  $\text{Der}_p$ .

Define:

$$\frac{\partial}{\partial x^i} \Big|_p : C^\infty(M) \rightarrow \mathbb{R}, \quad f \mapsto \frac{\partial f}{\partial x^i} \Big|_p = \partial_X f(p),$$

where  $X = \dot{c}$  and  $c(t) = \varphi^{-1}(\varphi(p) + te_i)$  ( $e_i$  is the  $i$ -th canonical basis vector). Note that, from the definition of the differential, it holds

$$\partial_X f(p) = (f \circ c)'(0) = \frac{\partial(f \circ \varphi^{-1})}{\partial x^i} \Big|_{\varphi(p)},$$

which shows that the object we defined can be seen as a partial derivative in the usual sense.

FIGURE 1.5: Isomorphism relations for the tangent space.

It can be shown that the set of derivations  $\{\frac{\partial}{\partial x^1}, \dots, \frac{\partial}{\partial x^n}\}$  forms a basis for  $\text{Der}_p$  and, due to the isomorphism, for  $T_p M$ ,  $X$  can be expressed as

$$X = X^i \frac{\partial}{\partial x^i},$$

where Einstein summation has been employed. Observe that linearity entails that

$$\partial_X f(p) = d_p f(X) = X^i d_p f \left( \frac{\partial}{\partial x^i} \Big|_p \right) = X^i \frac{\partial f}{\partial x^i} \Big|_p.$$

**1.1.11 Definition.** Let  $M$  be a manifold, we define a projection map  $\pi : TM \rightarrow M$  such that  $\pi(T_p M) = p$ , and we call a **section** in the tangent bundle a map  $s : M \rightarrow TM$  such that  $\pi \circ s = \text{id}_M$ .

The dual space of the tangent space  $T_p M$  is called the **cotangent space**, denoted with  $T_p^* M$ , which has a canonical basis denoted with  $\{dx^1|_p, \dots, dx^n|_p\}$ . The elements of such basis act on any element of the tangent space basis at  $p$  as follows:

$$dx^i|_p \left( \frac{\partial}{\partial x^j} \Big|_p \right) = \delta_{ij}.$$

Similarly is defined the **cotangent bundle**  $T^*M$  as the disjoint union of cotangent spaces.

**1.1.12 Definition.** Sections in the tangent bundle, denoted by  $C^\infty(M, TM)$ , are called **vector fields**, whereby sections in the cotangent bundle are called **1-forms**.

Vector fields are locally expressed in terms of linear combinations of

$$\left\{ \frac{\partial}{\partial x^1}, \dots, \frac{\partial}{\partial x^n} \right\} =: \{\partial_1, \dots, \partial_n\},$$

where  $\partial_i = \partial_i|_p$  at any point  $p$ , whereas 1-forms are expressed as linear combinations of

$$\{dx^1, \dots, dx^n\},$$

where  $dx^i$  is the 1-form that acts at  $p$  as  $dx^i|_p$ .

**1.1.13 Definition.** We define the derivative in the direction of  $X$  as an operator  $\partial_X : C^\infty(M) \rightarrow C^\infty(M)$  such that

$$\partial_X f = df(X),$$

for any vector field  $X \in C^\infty(M, TM)$ .

It follows immediately that Leibniz's rule holds:  $\partial_X(f \cdot g) = g \partial_X f + f \partial_X g$ , and again holds the useful formula

$$\partial_X f = df(X) = X^i df(\partial_i) = X^i \frac{\partial f}{\partial x^i}.$$

**1.1.14 Observation.** Given two vector fields  $X, Y \in C^\infty(M, TM)$ , there is a unique vector field  $[X, Y] \in C^\infty(M, TM)$  such that

$$\partial_{[X, Y]} f = \partial_X \partial_Y f - \partial_Y \partial_X f$$

for all  $f \in C^\infty(M)$ . The map  $[\cdot, \cdot] : C^\infty(M, TM) \times C^\infty(M, TM) \rightarrow C^\infty(M, TM)$  is called the **Lie bracket**, it is bilinear, skew-symmetric and satisfies the *Jacobi identity*: for any  $X, Y, Z \in C^\infty(M, TM)$  holds

$$[[X, Y], Z] + [[Y, Z], X] + [[Z, X], Y] = 0.$$

**1.1.15 Definition.** An **affine connection** or **covariant derivative** on a manifold  $M$  is a bilinear map

$$\begin{aligned} \nabla : C^\infty(M, TM) \times C^\infty(M, TM) &\rightarrow C^\infty(M, TM) \\ (X, Y) &\mapsto \nabla_X Y, \end{aligned}$$

such that for all smooth functions  $f \in C^\infty(M)$  and all vector fields  $X, Y \in C^\infty(M, TM)$ :

- $\nabla_{fX} Y = f \nabla_X Y$ , i.e.,  $\nabla$  is  $C^\infty(M)$ -linear in the first variable;
- $\nabla_X f = \partial_X f$ ;

- $\nabla_X(fY) = Y\partial_X f + f\nabla_X Y$ , i.e.,  $\nabla$  satisfies the Leibniz rule in the second variable.

The covariant derivative on the direction of the basis vector fields  $\{\partial_1, \dots, \partial_n\}$  is indicated

$$\nabla_j := \nabla_{\partial_j}.$$

We are now ready to introduce metric structures on manifolds.

## 1.2 Lorentzian Manifolds

In this section we will follow the approach delineated in [4] and in [3, Ch. 1]. We start in the simple case of **Minkowski spacetime**.

**1.2.1 Definition.** Let  $V$  be an  $n$ -dimensional vector space. A **Lorentzian scalar product** is a nondegenerate symmetric bilinear form  $\langle \cdot, \cdot \rangle$  with signature  $(- + \dots +)$ , i.e. such that one can find a basis  $\{e_1, \dots, e_n\}$  such that

$$\langle e_1, e_1 \rangle = -1, \quad \langle e_i, e_j \rangle = \delta_{ij} \quad \text{if } i, j > 1.$$

The **Minkowski product**  $\langle x, y \rangle_0$ , defined by the formula

$$\langle x, y \rangle_0 = \eta_{ik} x^i y^k = -x_1 y_1 + x_2 y_2 + \dots + x_n y_n,$$

with  $\eta := \text{diag}(-1, 1, \dots, 1, 1)$  is the simplest example of Lorentzian scalar product on  $\mathbb{R}^n$ . The  $n$ -dimensional Minkowski space, denoted by  $\mathbb{M}^n$  is simply  $\mathbb{R}^n$  equipped with Minkowski product.

**1.2.2 Definition.** We call the **negative squared length** of a vector  $X \in V$

$$\gamma(X) = -\|X\|^2 := -\langle X, X \rangle.$$

A vector  $X \in V \setminus \{0\}$  is called

- **timelike** if  $\gamma(X) > 0$ ,
- **lightlike** if  $\gamma(X) = 0$ ,
- **spacelike** if  $\gamma(X) < 0$  or  $X = 0$ ,
- **causal** if it is either timelike or lightlike.

FIGURE 1.6: Minkowski time orientation.

This definition will mostly be used for tangent vectors, in case  $V$  is the tangent space of a Lorentzian manifold at a point.

For  $n \geq 2$  the set of timelike vectors  $I(0)$  consists of two connected components. A **time orientation** is the choice of one of these two components, that we call  $I_+(0)$ .

**1.2.3 Definition.** We call

- $J_+(0) := \overline{I_+(0)}$  (elements are called **future-directed**),
- $C_+(0) := \partial I_+(0)$  (upper **light cone**),
- $I_-(0) := -I_+(0)$ ,  $J_-(0) := -J_+(0)$  (elements are called **past-directed**),
- $C_-(0) := -C_+(0)$  (lower **light cone**).

**1.2.4 Definition.** A **metric**  $g$  on a manifold  $M$  is the assignment of a scalar product at each tangent space

$$g : T_p M \times T_p M \rightarrow \mathbb{R}$$

which depends smoothly on the base point  $p$ . We call it a **Riemannian metric** if the scalar product is pointwise positive definite, and a **Lorentzian metric** if it is a Lorentzian scalar product.

A pair  $(M, g)$ , where  $M$  is a manifold and  $g$  is a Lorentzian (Riemannian) metric is called a **Lorentzian (Riemannian) manifold**.

The request of smooth dependence on  $p$  may be specified as follows: given any chart  $\{U, \varphi = (x^1, \dots, x^n)\}$  about  $p$ , the functions  $g_{ij} : \varphi(U) \rightarrow \mathbb{R}$  defined by  $g_{ij} = g(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j})$ , for any  $i, j = 1, \dots, n$  should be differentiable. With respect to these coordinates one writes

$$g = \sum_{i,j} g_{ij} dx_i \otimes dx_j \equiv \sum_{i,j} g_{ij} dx_i dx_j.$$

The scalar product of two tangent vectors  $v, w \in T_p M$ , with coordinate chart  $\varphi = (x^1, \dots, x^n)$ , such that  $v = v^i \frac{\partial}{\partial x^i}$ ,  $w = w^j \frac{\partial}{\partial x^j}$  is

$$\langle v, w \rangle = g_{ij}(\varphi(p)) v^i w^j.$$

When the choice of the chart is clear we will often write, with abuse of notation  $g_{ij}(p) := g_{ij}(\varphi(p))$ . We will indicate  $(g^{ij})_{i,j=1,\dots,n} = (g_{ij})^{-1}$ .

The **negative squared length** of a tangent vector  $X$  at  $p \in M$  generalizes naturally as follows:

$$\gamma(X) = -\langle X, X \rangle. \quad (1.1)$$

From now on  $M$  will always indicate a **Lorentzian manifold**.

**1.2.5 Definition.** A vector field  $X \in C^\infty(M, TM)$  is called *timelike*, *spacelike*, *lightlike* or *causal*, if  $X(p)$  is *timelike*, *spacelike*, *lightlike* or *causal*, respectively, at every point  $p \in M$ .

A differentiable curve  $c : I \rightarrow M$  is called *timelike*, *lightlike*, *spacelike*, *causal*, *future-directed* or *past-directed* if  $\dot{c}(t) \in T_{c(t)} M$  is, for all  $t \in I$ , *timelike*, *lightlike*, *spacelike*, *causal*, *future-directed* or *past-directed*, respectively.

A Lorentzian manifold  $M$  is called **time-oriented** if there exists a nowhere vanishing timelike vector field on  $M$ . If a manifold is time-oriented, we refer to it as **spacetime**.

The **causality relations** on  $M$  are defined as follows. Let  $p, q \in M$ ,

- $p \ll q$  iff there exists a future-directed timelike curve from  $p$  to  $q$ ,
- $p < q$  iff there is a future-directed causal curve from  $p$  to  $q$ ,

(a) A time-oriented tangent space.

(b) A time-oriented manifold together with field lines of a timelike vector field  $X$ .

FIGURE 1.7: Time orientations.

- $p \leq q$  iff  $p < q$  or  $p = q$ .

The causality relation " $<$ " is a strict weak ordering and the relation " $\leq$ " makes the manifold a partially ordered set.

**1.2.6 Definition.** The **chronological future** of a point  $x \in M$  is the set  $I_+^M(x)$  of points that can be reached by future-directed timelike curves, i.e.

$$I_+^M(x) = \{y \in M \mid x < y\}.$$

The **causal future**  $J_+^M(x)$  of a point  $x \in M$  is the set of points that can be reached by future-directed causal curves from  $x$ , i.e.,

$$J_+^M(x) = \{y \in M \mid x \leq y\}.$$

Given a subset  $A \subset M$  the **chronological future** and the **causal future** of  $A$  are respectively

$$I_+^M(A) = \bigcup_{x \in A} I_+^M(x), \quad J_+^M(A) = \bigcup_{x \in A} J_+^M(x).$$

In a similar way, one defines the **chronological** and **causal pasts** of a point  $x$  of a subset  $A \subset M$  by replacing future-directed curves with past directed curves. They are denoted by  $I_-^M(x)$ ,  $I_-^M(A)$ ,  $J_-^M(x)$ , and  $J_-^M(A)$ , respectively. We will also use the notation  $J^M(A) := J_-^M(A) \cup J_+^M(A)$ .

Any subset  $\Omega$  of a spacetime  $M$  is a spacetime itself, if one restricts the metric to  $\Omega$ . So  $I_{\pm}^{\Omega}(x)$  and  $J_{\pm}^{\Omega}(x)$  are well defined.

**1.2.7 Definition.** A subset  $\Omega \subset M$  of a spacetime is called **causally compatible** if for any point  $x \in \Omega$  holds

$$J_{\pm}^{\Omega}(x) = J_{\pm}^M(x) \cap \Omega,$$

where it can be noted that the inclusion " $\subset$ " always holds.

The condition we defined means that taken two points in  $\Omega$  that can be joined by a causal curve in  $M$ , there also exists a causal curve connecting them inside  $\Omega$ .

FIGURE 1.8: Causal future  $J_+^M$  and causal past  $J_-^M$  of a subset  $A \subset M$ .

We now can introduce the concept of **geodesics** and **exponential map**.

**1.2.8 Definition.** Let  $c : [a, b] \rightarrow M$  be a curve on a Lorentzian manifold  $M$ . The length  $L\dot{c}$  is defined by (with Einstein summation convention )

$$L\dot{c} = \int_a^b \sqrt{|g(\dot{c}(t), \dot{c}(t))|} dt = \int_a^b \sqrt{\left| g_{ik}(c(t)) \frac{dx^i}{dt} \frac{dx^k}{dt} \right|} dt,$$

where  $x^i(t) := (\varphi \circ c)^i(t)$  are the coordinates of the point  $c(t)$  in a chart  $\varphi$ . Given  $p, q \in M$ , if  $p \leq q$  we define the **time-separation** between  $p$  and  $q$  as

$$\tau(p, q) = \sup\{L[c] \mid c \text{ is a future directed causal curve from } p \text{ to } q\},$$

and 0 otherwise.

A **geodesic** between two points  $p, q \in M$  such that  $p \leq q$ , if it exists, is a curve  $c$  such that  $L[c] = \tau(p, q)$ , i.e. the curve of maximum time-separation.

The request on the geodesics implies that (in variational sense)  $\delta L\dot{c} = 0$ . It can be demonstrated that the stationary problem for the functional  $L\dot{c}$  is equivalent to  $\delta E\dot{c} = 0$  for the functional, called **energy**, defined by

$$E\dot{c} = \frac{1}{2} \int_a^b |g(\dot{c}(t), \dot{c}(t))| dt.$$

Since the Euler-Lagrange equations for a functional  $I[c] = \int_a^b f(t, c(t), \dot{c}(t)) dt$  read

$$\frac{d}{dt} \left( \frac{\partial f}{\partial \dot{x}^i} \right) - \frac{\partial f}{\partial x^i} = 0,$$

being  $c = (x^1, \dots, x^n)$ , then, in our case, setting  $f(t, c, \dot{c}) = g(\dot{c}, \dot{c})$ :

$$\frac{d^2 x^i}{dt^2} - \Gamma_{jk}^i \frac{dx^j}{dt} \frac{dx^k}{dt} = 0.$$

Here  $\Gamma_{jk}^i \in C^\infty(U \subset M)$  are the **Christoffel symbols**, defined in the chart  $\varphi = (\xi^1, \dots, \xi^n)$  as

$$\Gamma_{jk}^i = \frac{1}{2} \sum_l g^{il} \left( \frac{\partial g_{lj}}{\partial \xi^k} + \frac{\partial g_{lk}}{\partial \xi^j} - \frac{\partial g_{jk}}{\partial \xi^l} \right).$$

**1.2.9 Definition.** A connection  $\nabla$  on a manifold  $M$  with a metric  $g$  is said to be a **metric connection** if for all  $X, Y, Z \in C^\infty(M, TM)$  holds the following Leibniz rule:

$$\partial_X g(Y, Z) = g(\nabla_X Y, Z) + g(Y, \nabla_X Z).$$

The unique metric connection which is also torsion-free, i.e.,

$$T := \nabla_X Y - \nabla_Y X - [X, Y] = 0,$$

is called the **Levi-Civita connection**.

Another way to define **geodesics** is to say a geodesic between two points  $p, q$  on a manifold  $M$  with the Levi-Civita connection  $\nabla$  is the curve  $c$  which links  $p$  and  $q$  such that parallel transport along it preserves the tangent vector to the curve, i.e.

$$\nabla_{\dot{c}(t)} \dot{c}(t) = 0 \quad \text{for all } t \in [a, b]. \quad (1.2)$$

More precisely, in order to define the covariant derivative of  $\dot{c}$  it is necessary first to extend  $\dot{c}$  to a smooth vector field in an open set containing the image of the curve, but it can be shown that the derivative is independent of the choice of the extension.

**1.2.10 Observation.** We can express the Christoffel symbols in terms of the Levi-Civita connection:

$$\nabla_j \partial_k = \Gamma_{jk}^i \partial_i \quad (1.3)$$

in a local chart  $\varphi = (x^1, \dots, x^n)$ .

**1.2.11 Proposition.** Let  $\nabla$  be a connection over a manifold  $M$  and  $X, Y \in C^\infty(M, TM)$  be vector fields. It holds

$$\nabla_X Y = \left( X^j \partial_j Y^k + X^j Y^i \Gamma_{ij}^k \right) \partial_k,$$

in particular

$$(\nabla_j Y)^i = \partial_j Y^i + Y^i \Gamma_{ij}^k.$$

**Proof.** From Definition 1.1.15 holds:

$$\begin{aligned} \nabla_X Y &= \nabla_{X^j e_j} Y^i e_i = X^j \partial_j Y^i e_i = X^j Y^i \nabla_j e_i + X^j e_i \partial_j Y^i = \\ &= X^j Y^i \Gamma_{ij}^k e_k + (X^j \partial_j Y^k) e_k. \end{aligned}$$

**1.2.12 Proposition.** Let us consider  $p \in M$  and a tangent vector  $\xi \in T_p M$ . Then there exists  $\varepsilon > 0$  and precisely one geodesic

$$c_\xi : [0, \varepsilon] \rightarrow M,$$

such that  $c_\xi(0) = p$  and  $\dot{c}_\xi(0) = \xi$ .

**1.2.13 Definition.** In the conditions of the proposition above, if we put

$$\mathcal{D}_p = \{ \xi \in T_p M \mid c_\xi \text{ is defined on } [0, 1] \} \subset T_p M,$$

the **exponential map** at point  $p$  is defined as  $\exp_p : \mathcal{D}_p \rightarrow M$  such that  $\exp_p(\xi) = c_\xi(1)$ .

The local coordinates defined by the chart  $\{U := \exp_p(\mathcal{D}_p), \exp_p^{-1}\}$  are called **normal coordinates** centered at  $p$ .

**1.2.14 Proposition.** Given normal coordinates centered at  $p \in M$ , it holds

$$g_{ij}(p) := g_{ij}(\exp_p(0)) = \eta_{ij},$$

$$\Gamma_{jk}^i = 0,$$

for all indexes  $i, j, k$ .

FIGURE 1.9: The exponential maps from the tangent space to the manifold.

We are now ready to talk about **geodesically starshaped** sets.

**1.2.15 Definition.** An open subset  $\Omega \subset M$  is called **geodesically starshaped** with respect to a point  $p \in M$  if there exists an open subset  $\Omega' \subset T_p M$ , starshaped with respect to 0, such that the exponential map

$$\exp_p|_{\Omega'} : \Omega' \rightarrow \Omega,$$

is a diffeomorphism. If  $\Omega$  is geodesically starshaped with respect to all of its points, one calls it **convex**.

**1.2.16 Proposition.** Under the conditions of the last definition, let  $\Omega \subset M$  be geodesically starshaped with respect to point  $p \in M$ . Then one has

$$I_{\pm}^{\Omega}(p) = \exp_p(I_{\pm}(0) \cap \Omega'),$$

$$J_{\pm}^{\Omega}(p) = \exp_p(J_{\pm}(0) \cap \Omega').$$

We continue our preparations with another function that we are going to need in Chapter (3).

**1.2.17 Definition.** Let  $\Omega \subset M$  be open and geodesically starshaped with respect to  $x \in \Omega$ . We define

$$\Gamma_x := \gamma \circ \exp_x^{-1} : \Omega \rightarrow \mathbb{R},$$

where  $\gamma : T_x M \rightarrow \mathbb{R}$  is defined in equation (1.1).

### 1.2.1 Causality and Global Hyperbolicity

Now we introduce causal domains, because they will appear in the theory of wave equations. The local construction of fundamental solutions is always possible on causal domains, provided they are small enough.

**1.2.18 Definition.** A domain  $\Omega \subset M$  is called **causal** if its closure  $\overline{\Omega}$  is contained in a convex domain  $\Omega'$  and for any  $p, q \in \overline{\Omega}$   $J_+^{\Omega'}(p) \cap J_-^{\Omega'}(q)$  is compact and contained in  $\overline{\Omega}$ .

A subset  $A \subset M$  is called **past-compact** (respectively **future-compact**) if, for all  $p \in M$ ,  $A \cap J_-^M(p)$  (respectively  $A \cap J_+^M(p)$ ) is compact.

FIGURE 1.10: Convex, but non causal, domain

We can notice that, if we look at compact spacetimes, something physically unsound occurs:

**1.2.19 Proposition.** If a spacetime  $M$  is compact, there exists a closed timelike curve in  $M$ .

In a few words, there are manifolds, such as compact spacetimes, where there are timelike loops that can produce science fictional paradoxes. To avoid such unphysical and unrealistic things we require suitable causality conditions:

**1.2.20 Definition.** A spacetime satisfies the **causality condition** if it does not contain any closed causal curve. A spacetime  $M$  satisfies the **strong causality condition** if there are no almost closed causal curves, i.e. if for any  $p \in M$  there exists a neighborhood  $U$  of  $p$  such that there exists no timelike curve that passes through  $U$  more than once.

It is clear that the strong causality condition implies the causality condition.

FIGURE 1.11: Causal domain

FIGURE 1.12: Hypersurfaces.

**1.2.21 Definition.** A spacetime  $M$  that satisfies the strong causality condition and such that for all  $p, q \in M$   $J_+^M(p) \cap J_-^M(q)$  is compact is called **globally hyperbolic**.

It can be demonstrated that in globally hyperbolic manifolds for any  $p \in M$  and any compact set  $K \subset M$  the sets  $J_\pm^M(p)$  and  $J_\pm^M(K)$  are closed.

**1.2.22 Definition.** A subset  $S$  of a connected time-oriented Lorentzian manifold  $M$  is a **Cauchy hypersurface** if each inextendible timelike curve (i.e. no reparametrisation of the curve can be continuously extended) in  $M$  meets  $S$  at exactly one point.

In other words, no point of a Cauchy hypersurface is in the light cone of another point of the surface.

**1.2.23 Theorem.** Let  $M$  be a connected time-oriented Lorentzian manifold. Then the following are equivalent:

- $M$  is globally hyperbolic.

- There exists a Cauchy hypersurface in  $M$ .
- $M$  is isometric to  $\mathbb{R} \times S$  with metric  $g = -\beta dt^2 + b_t$ , where  $\beta$  is a smooth positive function,  $b_t$  is a Riemannian metric on  $S$  depending smoothly on  $t$  and each  $\{t\} \times S$  is a smooth Cauchy hypersurface in  $M$ .

In such case there exists a smooth function  $h : M \rightarrow \mathbb{R}$  whose gradient is past-directed timelike at every point and all of whose level sets are Cauchy hypersurfaces.

We briefly give some examples of globally hyperbolic spacetimes.

**1.2.24 Example.** The Minkowski spacetime  $\mathbb{M}^n$  is globally hyperbolic. Every spacelike hyperplane is a Cauchy hypersurface. We have  $\mathbb{M}^n = \mathbb{R} \times S$  with  $S = \mathbb{R}^{n-1}$ , endowed with the time-independent Euclidean metric.

Let  $S$  be a Riemannian manifold with time independent metric  $b_t$  and  $I \subset \mathbb{R}$  an interval. Let  $f : I \rightarrow \mathbb{R}$  be a smooth positive function. The manifold  $M = I \times S$  with the metric  $g = -dt^2 + f^2(t) b_t$ , called **cosmological spacetime**, is globally hyperbolic if and only if  $S$  is a complete space, see [2, Lem A.5.14]. This applies in particular if  $S$  is compact.

The interior and exterior **Schwartzschild spacetimes**, that represent non-rotating black holes of mass  $m > 0$  are globally hyperbolic. Denoting  $S^2$  the 2-dimensional sphere embedded in  $\mathbb{R}^3$ , we set

$$M_{\text{ext}} := \mathbb{R} \times (2m, +\infty) \times S^2,$$

$$M_{\text{int}} := \mathbb{R} \times (0, 2m) \times S^2.$$

The metric is given by

$$g = -h(r)dt^2 + \frac{1}{h(r)}dr^2 + r^2 g_{S^2},$$

where  $h(r) = 1 - \frac{2m}{r}$ , while  $g_{S^2} = r^2 d\vartheta^2 + r^2 \sin^2 \vartheta d\varphi^2$  is the polar coordinates metric on the sphere. For the exterior Schwartzschild spacetime we have  $M_{\text{ext}} = \mathbb{R} \times S$  with  $S = (2m, +\infty) \times S^2$ ,  $\beta = h$  and  $b_t = \frac{1}{h(r)}dr^2 + r^2 g_{S^2}$ .

### 1.3 Operators and integration on manifolds

We call  $C_0^\infty(M)$  the set of  $C^\infty$  functions on a manifold with compact support. The integral map<sup>1</sup> is defined as the unique map

$$\int_M \cdot d\mu : C_0^\infty(M) \rightarrow \mathbb{C},$$

such that it is linear and for any local chart  $\{U, \varphi\}$  and for any  $f \in C_0^\infty(U)$  holds

$$\int_M f d\mu = \int_{\varphi(U)} (f \circ \varphi^{-1})(x) \mu_x dx,$$

where we define

$$\mu_x := |\det g(x)|^{1/2}. \quad (1.4)$$

In this section we introduce the **generalized d'Alembert** operators, whose general form in local coordinates is given by

$$P = -g^{ij}(x) \frac{\partial^2}{\partial x^i \partial x^j} + a_j(x) \frac{\partial}{\partial x^j} + b(x). \quad (1.5)$$

The d'Alembert wave operator  $\square$  is defined for smooth functions  $f$  as

$$\square f = -\operatorname{div} \operatorname{grad} f,$$

where  $\operatorname{grad} f$  is a vector field defined by the requirement that the formula

$$\langle \operatorname{grad} f, X \rangle = \partial_X f$$

holds for any vector field  $X$ . At the same time  $\operatorname{div}$  is defined as follows

**1.3.1 Definition.** The **divergence** of a vector field  $Z = Z^i \partial_i$  is defined as

$$\operatorname{div} Z = \sum_j (\nabla_j Z)_j = \partial_j Z^j + \Gamma_{ij}^i Z^j.$$

**1.3.2 Proposition.** The following formula holds:

$$\operatorname{div} Z = \mu_x^{-1} \frac{\partial}{\partial x^j} (\mu_x Z^j), \quad (1.6)$$

and the definition of divergence is consistent with that of integral.

---

<sup>1</sup>see [2, Ch. A.3]

**Proof.** Let  $h \in C_0^\infty(M)$ ; using integration by parts

$$\int_M h \cdot \operatorname{div}(Z) d\mu = - \int_M Z^j \partial_j h d\mu = - \int_M Z^j \partial_j h \mu_x dx.$$

Now integrating by parts again in the chart it holds:

$$- \int_M \partial_j h Z^j \mu_x dx = \int_M h \partial_j (\mu_x Z^j) dx = \int_M h \mu_x^{-1} \partial_j (\mu_x Z^j) d\mu.$$

Since this is true for any function  $h$ , the formula is proven. ■

From the definition of gradient one can show

$$g_{ij}(\operatorname{grad} f)^i X^j = \partial_X f = X^j \frac{\partial f}{\partial x^j}, \quad \operatorname{grad} f = g^{ij} \frac{\partial f}{\partial x^i} \partial_j.$$

Hence it holds

$$\square f = -\mu_x^{-1} \frac{\partial}{\partial x^j} \left( \mu_x g^{ij} \frac{\partial f}{\partial x^i} \right).$$

In Minkowski spacetime, where  $g = \eta$ ,

$$\square f = -\frac{\partial}{\partial x^j} \left( \eta^{jj} \frac{\partial f}{\partial x^j} \right) = \frac{\partial^2 f}{\partial t^2} - \sum_{i=1}^{n-1} \frac{\partial^2 f}{\partial x_i^2} = -\partial^i \partial_i f.$$

In this chapter, we illustrate the concept of fundamental solutions and their use in solving initial value problems. We focus on the case of the d'Alembert wave operator  $\square$  built on top of the  $n$ -dimensional Minkowski spacetime  $\mathbb{M}^n$ . Two different approaches will be followed. The first relies on the Fourier transform. It is useful to build explicit formulas for the fundamental solutions in the lower dimensional cases and to show the existence of such solutions in the general case. The second approach, via Riesz distributions, is useful for its generality and because it will be used in the next chapter to construct fundamental solutions on suitable Lorentzian manifolds, although it is more abstract and does not lead to explicit formulas.

We will find two independent fundamental solutions, the *retarded* and the *advanced* one, that preserve the causal structure of the spacetime, i.e. that propagate the source of the equation respectively in the causal future and in the causal past, in accordance with the causality principle.

## 2.1 Fundamental solutions

**2.1.1 Definition.** Let  $P$  be a differential operator on a manifold  $M$  and  $x_0 \in M$ . A **fundamental solution** for  $P$  at  $x_0$  is a distribution  $u_{x_0} \in \mathcal{D}'(M)$  such that

$$Pu_{x_0} = \delta_{x_0},$$

where  $\delta_{x_0}$  is the Dirac delta distribution in  $x_0$ , i.e.  $(\delta_{x_0}, f) = f(x_0)$  for all  $f \in \mathcal{D}(\mathbb{M})$ .

Following the previous definition<sup>1</sup>, assume that a fundamental solution  $u_x$  has a continuous dependence on  $x$  (i.e. the function  $x \mapsto (u_x, \varphi)$  is continuous for all  $\varphi \in \mathcal{D}(\mathbb{M})$ ) and  $\psi \in \mathcal{D}(\mathbb{M})$ , then  $F_\psi := (u_x, \psi)$  is a solution for the differential equation

$$PF_\psi = \psi.$$

This comes applying the operator  $P$  on  $F_\psi$ , for which one obtains

$$PF_\psi = (u_x, P^*\psi) = (Pu_x, \psi) = (\delta_x, \psi) = \psi(x),$$

where  $P^*$  stands for the formal adjoint of  $P$ .

## 2.2 The d'Alembert wave operator in Minkowski

In order to be more concrete, we begin by computing the fundamental solution of  $\square$  in  $\mathbb{M}^n$  with  $2 \leq n \leq 4$ .

As we recalled in the previous chapter, the d'Alembert wave operator is defined in  $\mathbb{M}^n$ , with respect to the variables  $x = (t, \mathbf{x})$ , as

$$\square := \frac{\partial^2}{\partial t^2} - \sum_{i=1}^{n-1} \frac{\partial^2}{\partial x_i^2} = -\partial^i \partial_i.$$

We will find two fundamental solutions  $G_{x_0}^+, G_{x_0}^- \in \mathcal{D}'(\mathbb{M}^n)$  for  $\square$  at  $x_0 \in \mathbb{M}^n$  with the following properties

$$\text{supp}(G_{x_0}^+) \subset J_+(x_0), \quad \text{supp}(G_{x_0}^-) \subset J_-(x_0). \quad (2.1)$$

Such solutions will be called respectively **retarded** ( $G_+$ ) and **advanced** ( $G_-$ ) fundamental solutions.

In order to find the fundamental solutions at  $x_0$ , the following proposition guarantees it suffices to solve the problem  $\square u_0 = \delta_0$ .

**2.2.1 Proposition.** *Let  $x_0 \in \mathbb{M}^n$  and  $T_{x_0}$  be the translation operator as in Definition A.0.3. Then  $[\square, T_{x_0}] = 0$  (i.e.  $\square$  and  $T_{x_0}$  commute) and a fundamental solution for  $\square$  at  $x_0$  is*

$$u_{x_0} = T_{x_0} u_0,$$

where  $u_0$  is a fundamental solution at 0.

---

<sup>1</sup>see [3, Ch. 2] and [5]

**Proof.** Let  $\varphi \in \mathcal{D}(\mathbb{M}^n)$ , then

$$\begin{aligned} (\square T_{x_0} u, \varphi(x)) &= (T_{x_0} u, \square \varphi(x)) = (u, \square \varphi(x + x_0)) = \\ &= (\square u, \varphi(x + x_0)) = (T_{x_0} \square u, \varphi(x)), \end{aligned}$$

where it was used the fact that  $\square$  is formally self-adjoint and invariant under translations when acting on smooth functions. Hence, it holds

$$\square(T_{x_0} u_0) = T_{x_0}(\square u_0) = T_{x_0} \delta_0 = \delta_{x_0},$$

because  $\square$  and  $T_{x_0}$  commute, so  $T_{x_0} u_0$  is a fundamental solution at  $x_0$ . ■

**2.2.2 Proposition.** Let  $\psi \in \mathcal{D}(\mathbb{M}^n)$ . Then

$$F_\psi = u_0 * \psi \in C^\infty(\mathbb{M}^n) \quad (2.2)$$

is a (smooth) solution for the differential equation  $PF_\psi = \psi$  (here  $*$  denotes convolution).

**Proof.** Since  $u_x = T_x u_0$  and  $F_\psi = (u_x, \psi) = (T_x u_0, \psi)$  is a solution to the equation, the thesis follows immediately noting that, by definition,  $(T_x u_0, \psi) = (u_0 * \psi)(x)$ . The smoothness of the solution follows from Theorem A.0.7. ■

## 2.3 The Fourier transform approach

In order to employ the theory of Fourier transforms, it is necessary to work with distributions in  $\mathcal{S}'(\mathbb{M}^n)$ .

We shall begin with a lemma that helps in the computations:

**2.3.1 Lemma.** For  $u \in \mathcal{S}'(\mathbb{M}^n)$  if we let  $x = (t, \mathbf{x}) = (t, x_1, \dots, x_{n-1})$  and  $k = (\omega, \mathbf{k}) = (\omega, k_1, \dots, k_{n-1})$ , it holds

$$\widehat{\square u}(k) = \|k\|^2 \widehat{u} = (|\mathbf{k}|^2 - \omega^2) \widehat{u}(k). \quad (2.3)$$

**Proof.** For any test function  $f \in \mathcal{S}(\mathbb{M}^n)$ , and for any  $u \in \mathcal{S}'(\mathbb{M}^n)$   $(\square u, f) = (u, \square f)$ . Note that

$$\begin{aligned} \square_x \widehat{f}(k) &= \int_{\mathbb{R}^n} \square_x f(x) e^{-i\langle k, x \rangle_0} dx = \\ &= \int_{\mathbb{R}^n} f(x) (|\mathbf{k}|^2 - \omega^2) e^{-i\langle k, x \rangle_0} dx = (|\mathbf{k}|^2 - \omega^2) \widehat{f}(k) \end{aligned}$$

from which it descends

$$(\widehat{\square}u, f) = (\square u, \widehat{f}) = (u, \square \widehat{f}) = (|\mathbf{k}|^2 - \omega^2)(\widehat{u}, f).$$

■

Following [10, Ch. 5], we start by transforming the equation:

$$\widehat{\square}u(k) = \widehat{\delta}(k) \Rightarrow (|\mathbf{k}|^2 - \omega^2)\widehat{u}(k) = 1 \quad (2.4)$$

The difference of two solutions  $\widehat{u} \in \mathcal{S}'(\mathbb{M}^n)$ , is a solution  $\widehat{v}$  to the equation

$$(|\mathbf{k}|^2 - \omega^2)\widehat{v}(k) = 0. \quad (2.5)$$

This equation can be seen as the Fourier transform of the correspondent homogeneous equation  $\square v = 0$ . Hence  $\widehat{u} + \widehat{v}$  is the transform of the sum of a particular solution for  $\square$  and a solution of the homogeneous equation, then it is a solution for Equation (2.4).

If we concentrate on the solutions for Equation (2.5), it is easy to see with a direct computation that any distribution of the form

$$\widehat{v}(k) = A(k)\delta(|\mathbf{k}|^2 - \omega^2),$$

where  $A(k)$  is any suitably regular function of  $k$ , solves the equation, because the Dirac delta is supported on  $\{k \in \mathbb{R}^n \mid |\mathbf{k}|^2 - \omega^2 = 0\}$ . Any solution to the homogeneous wave equation can be obtained by the inverse transform of  $\widehat{v}$ :

$$v(x) = (2\pi)^{-n} \int_{\mathbb{R}^n} e^{i\langle k, x \rangle_0} A(k) \delta(|\mathbf{k}|^2 - \omega^2) dk.$$

Making use of formula (A.1), the last expression becomes

$$\begin{aligned} v(x) &= (2\pi)^{-n} \int_{\mathbb{R}^n} e^{i\langle k, x \rangle_0} \frac{A(k)}{2|\mathbf{k}|} [\delta(|\mathbf{k}| - \omega) + \delta(|\mathbf{k}| + \omega)] dk = \\ &= (2\pi)^{-n} \int_{\mathbb{R}^{n-1}} d\mathbf{k} e^{i\mathbf{k} \cdot \mathbf{x}} \frac{e^{i|\mathbf{k}|t} A(k)|_{|\mathbf{k}|=\omega} + e^{-i|\mathbf{k}|t} A(k)|_{|\mathbf{k}|=-\omega}}{|\mathbf{k}|}. \end{aligned} \quad (2.6)$$

To solve for  $\widehat{u}$  it is tempting to write

$$\widehat{u}(k) = \frac{1}{|\mathbf{k}|^2 - \omega^2} = \frac{1}{(|\mathbf{k}| - \omega)(|\mathbf{k}| + \omega)},$$

which is ill-defined as a distribution wherever  $\langle k, k \rangle_0 = 0$ , i.e. on the light-cone of the Fourier space. Hence, we will define  $\widehat{u}$  as limit of a sequence of distributions depending on the parameter  $\varepsilon$

$$\widehat{u}_\varepsilon = \frac{1}{|\mathbf{k}|^2 - (\omega \pm i\varepsilon)^2} = \frac{1}{(|\mathbf{k}| \mp i\varepsilon - \omega)(|\mathbf{k}| \pm i\varepsilon + \omega)}$$

promoting  $\omega$  to a complex variable and taking the limit for  $\varepsilon \rightarrow 0^+$  after performing the inverse transform. The choice of the signs in such expressions leads to different fundamental solutions.

## 2.4 Fundamental solutions via Fourier transform

The distributions  $G_+$  and  $G_-$  in  $\mathcal{S}'(\mathbb{M}^n)$ , defined respectively as the weak limit for  $\varepsilon \rightarrow 0^+$  of

$$G_\varepsilon^+(x) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} \frac{e^{i\langle k, x \rangle_0}}{|\mathbf{k}|^2 - (\omega + i\varepsilon)^2} dk, \quad (2.7)$$

$$G_\varepsilon^-(x) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^n} \frac{e^{i\langle k, x \rangle_0}}{|\mathbf{k}|^2 - (\omega - i\varepsilon)^2} dk, \quad (2.8)$$

are respectively a **retarded** and an **advanced** fundamental solutions at  $x_0 = 0$  for the d'Alembert wave operator.

The aim is to prove that  $\text{supp}(G_+) \subset J_+(0)$  and  $\text{supp}(G_-) \subset J_-(0)$ , and we proceed firstly by calculating the explicit formula for  $2 \leq n \leq 4$  and then discuss the general case via Riesz distributions.

We compute  $G_\pm$  as a limit of the inverse of the Fourier transform:

$$\begin{aligned} G_\varepsilon^\pm(x) &= (2\pi)^{-n} \int_{\mathbb{R}^n} \frac{e^{i\langle k, x \rangle_0}}{|\mathbf{k}|^2 - (\omega \pm i\varepsilon)^2} dk \\ &= (2\pi)^{-n} \int_{\mathbb{R}^{n-1}} d\mathbf{k} e^{i\mathbf{k} \cdot \mathbf{x}} \int_{-\infty}^{+\infty} \frac{e^{-i\omega t}}{|\mathbf{k}|^2 - (\omega \pm i\varepsilon)^2} d\omega. \end{aligned} \quad (2.9)$$

### Computing the complex integrals

In order to calculate the inner integral in the former expression,

$$\tilde{G}_\varepsilon^\pm(t, \mathbf{k}) := \int_{-\infty}^{+\infty} \frac{e^{-i\omega t}}{|\mathbf{k}|^2 - (\omega \pm i\varepsilon)^2} d\omega,$$

we make use of techniques of complex analysis as follows.

Denote

 FIGURE 2.1: The circuit to compute  $\tilde{G}_\varepsilon^+(t, \mathbf{k})$  for  $t > 0$ .

- $C_\rho^+$  the upper half-circle of radius  $\rho$  centered at  $\omega = 0$  which has  $\text{Im}(\omega) > 0$ , oriented counter-clockwise;
- $C_\rho^-$  the lower half-circle of radius  $\rho$  centered at  $\omega = 0$  which has  $\text{Im}(\omega) < 0$ , oriented clockwise;
- $[-\rho, \rho]$  the interval of the real line connecting  $-\rho$  and  $\rho$ , oriented from left to right.

 FIGURE 2.2: The circuit to compute  $\tilde{G}_\varepsilon^-(t, \mathbf{k})$  for  $t < 0$ .

The singularities are

$$\text{for } \tilde{G}_\varepsilon^+ : \quad \omega = \pm|\mathbf{k}| - i\varepsilon,$$

$$\text{for } \tilde{G}_\varepsilon^- : \quad \omega = \pm|\mathbf{k}| + i\varepsilon.$$

Hence we have

$$\text{for } t < 0 \quad \tilde{G}_\varepsilon^+(t, \mathbf{k}) = \lim_{\rho \rightarrow \infty} \int_{C_\rho^+ + [-\rho, \rho]} \frac{e^{-i\omega t}}{|\mathbf{k}|^2 - (\omega + i\varepsilon)^2} d\omega = 2\pi i \sum \text{Res} = 0,$$

where the sum is extended to the singularities in the upper half-plane. The expression vanishes because we choose the circuit such that the integral on  $C_\rho^+$  vanishes in virtue of Jordan's lemma and there are no singularities in the region bounded by the circuit.

For the same reasons

$$\text{for } t > 0, \quad \tilde{G}_\varepsilon^-(t, \mathbf{k}) = \lim_{\rho \rightarrow \infty} \int_{C_\rho^- + [-\rho, \rho]} \frac{e^{-i\omega t}}{|\mathbf{k}|^2 - (\omega - i\varepsilon)^2} d\omega = -2\pi i \sum \text{Res} = 0,$$

where the sum is extended to the singularities of the function in the lower half-plane and the minus sign arises because of the clockwise circuit.

The non-zero integrals are

$$\tilde{G}_\varepsilon^+(t, \mathbf{k}), \text{ for } t > 0, \quad \tilde{G}_\varepsilon^-(t, \mathbf{k}), \text{ for } t < 0.$$

The first is computed via the lower circuit in FIGURE (2.1):  $C_\rho^- + [-\rho, \rho]$ , the second via the upper counterpart in FIGURE (2.2):  $C_\rho^+ + [-\rho, \rho]$ , in order to get rid of contributes from the half-circles.

The results are

$$\text{for } t > 0 \quad \tilde{G}_\varepsilon^+(t, \mathbf{k}) = 2\pi i e^{-\varepsilon|\mathbf{k}|t} \left( \frac{e^{-i|\mathbf{k}|t} - e^{i|\mathbf{k}|t}}{2|\mathbf{k}|} \right) = 2\pi \frac{\sin |\mathbf{k}|t}{|\mathbf{k}|} e^{-\varepsilon|\mathbf{k}|t},$$

$$\text{for } t < 0 \quad \tilde{G}_\varepsilon^-(t, \mathbf{k}) = -2\pi i e^{\varepsilon|\mathbf{k}|t} \left( \frac{e^{-i|\mathbf{k}|t} - e^{i|\mathbf{k}|t}}{2|\mathbf{k}|} \right) = -2\pi \frac{\sin |\mathbf{k}|t}{|\mathbf{k}|} e^{\varepsilon|\mathbf{k}|t}.$$

Summing up everything in one formula:

$$\tilde{G}_\varepsilon^\pm(t, \mathbf{k}) = \pm 2\pi \Theta(\pm t) \frac{\sin |\mathbf{k}|t}{|\mathbf{k}|} e^{\mp \varepsilon|\mathbf{k}|t}, \quad (2.10)$$

where  $\Theta$  is the Heaviside step-function.

It can be noticed that

$$\tilde{G}_\varepsilon^+(t, \mathbf{k}) = \tilde{G}_\varepsilon^-(-t, \mathbf{k}),$$

because of the parity of sine function. So, we can deduce that the **advanced** solution can be calculated from the retarded one via time inversion:

$$G_-(t, \mathbf{x}) = G_+(-t, \mathbf{x}). \quad (2.11)$$

We can now show that the support  $G_\pm$  is included in  $J_+(0) \cup J_-(0)$ .

**2.4.1 Proposition.** *If  $x \in \mathbb{M}^n$  satisfies  $\gamma(x) < 0$  (where  $\gamma$  is defined in Definition 1.2.2),  $G_{\pm}(x) = 0$ .*

**Proof.** Consider a reference frame  $R$  in which  $x = (t, \mathbf{x})$  and suppose for now  $t \geq 0$ . It descends  $G_+(x) = 0$ . Since  $G_{\pm}$  are manifestly Lorentz invariant and  $\gamma(x) < 0$ , one can find a reference frame  $R'$  in which  $x = (t', \mathbf{x}')$  and  $t' < 0$ , so that  $G_-(x) = 0$ . The converse can be treated similarly. ■

We can focus once more on equation (2.9) to show explicit solutions for spatial dimensions  $d$  ranging from 1 to 3:

$$\begin{aligned} G_{(d)}^+(x) &= \frac{1}{(2\pi)^{d+1}} \lim_{\varepsilon \rightarrow 0^+} \int_{\mathbb{R}^d} d\mathbf{k} e^{i\mathbf{k} \cdot \mathbf{x}} \tilde{G}_{\varepsilon}^+(t, \mathbf{k}) = \\ &= \lim_{\varepsilon \rightarrow 0^+} \frac{\Theta(t)}{(2\pi)^d} \int_{\mathbb{R}^d} d\mathbf{k} e^{i\mathbf{k} \cdot \mathbf{x}} \frac{\sin |\mathbf{k}|t}{|\mathbf{k}|} e^{-\varepsilon |\mathbf{k}|t}. \end{aligned}$$

### Dimension $n = 1 + 1$ - wave on a line

The integral we have to make is:

FIGURE 2.3: The support of  $G_+$  in 1+1 dimensional case.

$$G_{(1)}^+(t, x) = \frac{\Theta(t)}{2\pi} \lim_{\varepsilon \rightarrow 0^+} \int_{-\infty}^{+\infty} dk e^{ik \cdot x} \frac{\sin kt}{k} e^{-\varepsilon kt}.$$

It holds

$$\int_{-\infty}^{+\infty} dk e^{ik \cdot (x + i\varepsilon t)} \frac{\sin kt}{k} \xrightarrow{k \rightarrow k' = kt} \int_{-\infty}^{+\infty} dk e^{ik \cdot (x/t + i\varepsilon)} \frac{\sin k}{k} \xrightarrow{\varepsilon \rightarrow 0^+}$$

$$\longrightarrow \pi \chi_{[-1,1]} \left( \frac{x}{t} \right) = \pi \chi_{[-t,t]}(x),$$

where

$$\chi_{[a,b]}(z) = \begin{cases} 1, & \text{if } z \in [a, b] \\ 0, & \text{otherwise,} \end{cases}$$

Finally the integrals become

$$G_{(1)}^+(t, x) = \frac{\Theta(t)}{2} \chi_{[-t,t]}(x) = \frac{\Theta(t - |x|)}{2}.$$

FIGURE 2.4: The support of  $G_-$  in 1+1 dimensional case.

From FIGURES (2.3) and (2.4) one can infer that the fundamental solutions are supported respectively on  $J_+(0)$  and  $J_-(0)$ .

### Dimension $n = 1 + 2$ - wave on a surface

The integral is two dimensional:

$$G_{(2)}^+(t, \mathbf{x}) = \frac{\Theta(t)}{(2\pi)^2} \lim_{\varepsilon \rightarrow 0^+} \int_{\mathbb{R}^2} d\mathbf{k} e^{i\mathbf{k} \cdot \mathbf{x}} \frac{\sin |\mathbf{k}|t}{|\mathbf{k}|} e^{-\varepsilon |\mathbf{k}|t}.$$

To evaluate it we switch to polar coordinates  $\mathbf{k} = (k \cos \varphi, k \sin \varphi)$ . With the integral measure

$$d\mathbf{k} = k dk d\varphi,$$

the integral becomes ( $x := |\mathbf{x}|$ )

$$\int_0^{2\pi} d\varphi \int_0^{+\infty} dk e^{ikx \cos \varphi} \sin kt e^{-\varepsilon kt}.$$

It holds that

$$\begin{aligned} \int_0^\infty dk e^{ik(y+i\varepsilon)} \sin kt &= \frac{1}{2i} \left[ \int_0^{+\infty} e^{ik(y+i\varepsilon+t)} dk + \int_0^{+\infty} e^{ik(y+i\varepsilon-t)} dk \right] = \\ &= \frac{1}{2} [I_\varepsilon(y+t) + I_\varepsilon(y-t)], \end{aligned}$$

where we set  $I_\varepsilon(y) := \frac{1}{i} \int_0^{+\infty} e^{ik(y+i\varepsilon)} dk$ . Since

$$I_\varepsilon(y) = \frac{1}{i} \int_0^{+\infty} e^{ik(y+i\varepsilon)} dk = \frac{1}{y+i\varepsilon},$$

the integral which needs to be evaluated is

$$\frac{1}{2} \int_0^{2\pi} \left[ \frac{1}{x \cos \varphi + t + i\varepsilon} + \frac{1}{x \cos \varphi - t + i\varepsilon} \right] d\varphi.$$

Such integral has a counterpart over a unit circle in the complex plane with the substitutions  $d\varphi = -idz/z$  and  $\cos \varphi = (z + z^{-1})/2$ . Hence, using Cauchy residue theorem

$$\int_0^{2\pi} \frac{1}{x \cos \varphi \pm t + i\varepsilon} d\varphi = -2i \oint \frac{dz}{xz^2 + 2(\pm t + i\varepsilon)x + 1} = \frac{2\pi}{\sqrt{(t \mp i\varepsilon)^2 - x^2}}.$$

Putting everything together in the weak limit  $\varepsilon \rightarrow 0$  it holds

$$G_{(2)}^+(t, \mathbf{x}) = \frac{\Theta(t)}{2\pi} \frac{\Theta(t^2 - |\mathbf{x}|^2)}{\sqrt{t^2 - |\mathbf{x}|^2}} = \frac{\Theta(t)}{2\pi} \frac{\Theta(\gamma(x))}{\sqrt{\gamma(x)}}, \quad (2.12)$$

where  $\Theta(t^2 - |\mathbf{x}|^2)$  stems from Proposition 2.4.1. As a by-product,  $\text{supp}(G_\pm) \subseteq J_\pm(0)$ .

### Dimension $n = 1 + 3$ - spherical wave

The three-dimensional integral is

$$G_{(3)}^+(t, \mathbf{x}) = \frac{\Theta(t)}{(2\pi)^3} \lim_{\varepsilon \rightarrow 0^+} \int_{\mathbb{R}^3} d\mathbf{k} e^{i\mathbf{k} \cdot \mathbf{x}} \frac{\sin |\mathbf{k}|t}{|\mathbf{k}|} e^{-\varepsilon |\mathbf{k}|t}.$$

Again, we make a change of coordinate, switching to the spherical ones:  $\mathbf{k} = (k \sin \vartheta \cos \varphi, k \sin \vartheta \sin \varphi, k \cos \vartheta)$ . The integral measure reads

$$d\mathbf{k} = k^2 \sin \vartheta dk d\vartheta d\varphi$$

FIGURE 2.5: The level set  $G_{\pm}(\mathbf{x}, t) = 1$  in the 1+2 dimensional case, plotted for one spatial axis.

and the integral to calculate is ( $x := |\mathbf{x}|$ )

$$\int_0^{2\pi} d\varphi \int_0^{+\infty} dk k \sin kt \int_{-1}^1 e^{ikx \cos \vartheta} d(\cos \vartheta) = \frac{4\pi}{x + i\varepsilon} \int_0^{+\infty} \sin kt \sin k(x + i\varepsilon) dk.$$

Hence we can write using the exponential function

$$\sin kt \sin kx = \frac{1}{4} \left\{ \left[ e^{ik(x+i\varepsilon-t)} + e^{-ik(x+i\varepsilon-t)} \right] - \left[ e^{ik(x+i\varepsilon+t)} + e^{-ik(x+i\varepsilon+t)} \right] \right\},$$

and with the change of variables  $k \leftrightarrow -k$  it holds

$$\begin{aligned} \frac{4\pi}{x} \int_0^{+\infty} \sin kt \sin kx dk &= \frac{2\pi^2}{x} \frac{1}{2\pi} \int_{-\infty}^{+\infty} e^{ik(x+i\varepsilon-t)} - e^{ik(x+i\varepsilon+t)} dk \xrightarrow{\varepsilon \rightarrow 0^+} \\ &\longrightarrow \frac{2\pi^2}{x} [\delta(t-x) - \delta(t+x)]. \end{aligned}$$

To find the correct retarded and advanced fundamental solutions we notice that the second term,  $\delta(t+x)$ , vanishes for  $G_+$  because  $x > 0$  and  $t > 0$ . Conversely the first term  $\delta(t-x)$  vanishes when computing  $G_-$ . In view of these considerations, the general formula for the 1 + 3-case becomes

$$G_{(3)}^+(t, \mathbf{x}) = \frac{\Theta(t)}{4\pi} \frac{\delta(t - |\mathbf{x}|)}{|\mathbf{x}|}. \quad (2.13)$$

One can verify that  $G_{(3)}^\pm$  vanish outside the support of the delta distribution. Hence they are supported respectively on the upper and on the lower light cones  $C_+(0)$  and  $C_-(0)$ . This is a particularity of the odd spatial dimensions, as we shall prove in the next section. This feature is known as the **Huygens' principle**. It states that in general, we have for spatial dimensions  $d \neq 1$

$$\text{supp } G_{(d)}^\pm = J_\pm(0) \quad \text{for } d \text{ even,}$$

$$\text{supp } G_{(d)}^\pm = C_\pm(0) \quad \text{for } d \text{ odd.}$$

Physically, we can see  $\delta_0$  as a point source at 0 of a signal that propagates with constant speed. Inside the future light cone the solution is zero, so if  $d$  is even, the wave propagates strictly on the cone. In case  $d$  is odd, the signal of a point source propagates also inside the light cone. For an observer, the wave is noticeable not only at a single moment but still after the signal has arrived. An example of such waves are the 2-dimensional ones like water waves. For more on Huygens' principle, see [7] and [10, Ch. 5].

FIGURE 2.6: The support of  $G_+$  in 1+3 dimensional case, i.e. the upper light cone  $C_+(0)$ , plotted for two spatial axis.

### The method of *descent*<sup>2</sup>

The lower dimensional advanced and retarded distributions can be directly deduced from the  $d = 3$  case as we shall see. In general if we know the explicit

---

<sup>2</sup>see [8, Ch. 6] and [10, Ch. 5].

solution to the  $d$ -dimensional case we can find the  $d-1$ -dimensional counterpart with the formula

$$G_{(d-1)}^{\pm}(t, x_1, \dots, x_{d-1}) = \int_{-\infty}^{\infty} G_{(d)}^{\pm}(t, x_1, \dots, x_d) dx_d.$$

This technique is called *method of descent*. The last assertion can be proven taking the fundamental solution equation

$$\square_d G_{(d)}(t, x_1, \dots, x_d) = \delta(t)\delta(x_1) \cdots \delta(x_d),$$

where  $\square_d$  stands for  $(\partial_t^2 - \partial_1^2 - \cdots - \partial_d^2)$ . Integrating  $G_{(d)}$  on the last variable against a test-function  $\varphi \in \mathcal{D}(\mathbb{R})$ :

$$\begin{aligned} \int \square_d G_{(d)} \varphi dx_d &= \square_{(d-1)} \int G_{(d)} \varphi dx_d - \int \partial_d^2 G_{(d)} \varphi dx_d = \\ &= \delta(t)\delta(x_1) \cdots \delta(x_{d-1}) \int \delta(x_d) \varphi dx_d. \end{aligned}$$

By letting the test-function become a sequence of cut-off functions covering the real axis, the formula

$$\square_{(d-1)} \int G_{(d)} dx_d = \delta(t)\delta(x_1) \cdots \delta(x_{d-1})$$

is proven.

To calculate the  $d = 2$  fundamental solution from the  $d = 3$  case, according to (2.13) and using equation (A.1) we can write for the retarded fundamental solution

$$\begin{aligned} \Theta(t) \frac{\delta(t - |\mathbf{x}|)}{2|\mathbf{x}|} &= \Theta(t)\delta(t^2 - |\mathbf{x}|^2) = \Theta(t)\delta(t^2 - x_1^2 - x_2^2 - x_3^2) = \\ &= \Theta(t)\Theta(t^2 - x_1^2 - x_2^2) \frac{\delta(x_3 - \sqrt{t^2 - x_1^2 - x_2^2}) + \delta(x_3 + \sqrt{t^2 - x_1^2 - x_2^2})}{2\sqrt{t^2 - x_1^2 - x_2^2}}, \end{aligned}$$

where we insert the Heaviside step function to take into account Proposition 2.4.1. Hence, integrating over the third variable yields

$$G_{(2)}^+(t, x_1, x_2) = \frac{\Theta(t)}{2\pi} \frac{\Theta(t^2 - x_1^2 - x_2^2)}{\sqrt{t^2 - x_1^2 - x_2^2}},$$

which is identical to equation (2.12) as we expected. Similarly, the expression for the case  $d = 1$  can be derived again.

If we now apply to the general expression for  $G_{(d)}$  the Fourier transform in the last variable, similarly we obtain

$$\begin{aligned} & \int_{-\infty}^{+\infty} \partial_d^2 G_{(d)}(t, x_1, \dots, x_d) e^{-imx_d} dx_d = \\ & = -m^2 \int_{-\infty}^{+\infty} G_{(d)}(t, x_1, \dots, x_d) e^{-imx_d} dx_d =: -m^2 \widehat{G}_{d-1}(t, x_1, \dots, x_{d-1}, m). \end{aligned}$$

Hence, the Fourier transform on the last variable  $\widehat{G}_{d-1}(t, x_1, \dots, x_{d-1}, m)$  is, for a fixed  $m \in \mathbb{R}$ , a fundamental solution for the  $d-1$  dimensional **Klein-Gordon** operator

$$\square + m^2,$$

that describes the motion of spinless particles with mass  $m$ .

## 2.5 The Riesz distributions

To discuss explicit and useful formulas for the fundamental solution in the general  $n$ -dimensional case, the approach we adopted in the last section is not very effective. We outline a method devised by M. Riesz in the first half of the 20th century in order to find solutions to a certain class of differential equations. We will follow [5] and [3, Ch. 1.3].

**2.5.1 Definition.** For  $\alpha \in \mathbb{C}$  with  $\operatorname{Re} \alpha > n$  let  $R_{\pm}(\alpha)$  be the complex-valued continuous functions defined for any  $x \in \mathbb{M}^n$  by

$$R_{\pm}(\alpha)(x) := \begin{cases} C(\alpha, n) \gamma(x)^{\frac{\alpha-n}{2}} & \text{if } x \in J_{\pm}(0) \\ 0 & \text{otherwise,} \end{cases} \quad (2.14)$$

where  $\gamma$  is defined in Definition 1.2.2,

$$C(\alpha, n) := \frac{2^{1-\alpha} \pi^{\frac{2-n}{2}}}{\Gamma(\frac{\alpha}{2}) \Gamma(\frac{\alpha-n}{2} + 1)},$$

and  $z \mapsto \Gamma(z)$  is the Gamma function.

**2.5.2 Remark.** The functions  $R_{\pm}(\alpha)$  are continuous because  $\gamma = -\langle \cdot, \cdot \rangle_0$  vanishes on the boundary of  $J_{\pm}(0)$  and the exponent  $(\alpha - n)/2$  is assumed to have positive real part. If we increase the real part of the exponent then higher derivatives of the function vanishes at the boundary and the functions become more regular. As a matter of facts  $R_{\pm}(\alpha) \in C^k(\mathbb{M}^n)$  whenever  $\operatorname{Re} \alpha > n + 2k$ .

Now we discuss the first properties of  $R_{\pm}(\alpha)$ .

**2.5.3 Proposition.** *For all  $\alpha \in \mathbb{C}$  with  $\operatorname{Re} \alpha > n$  it holds*

- (1)  $\gamma R_{\pm}(\alpha) = \alpha(\alpha - n + 2)R_{\pm}(\alpha + 2);$
- (2)  $(\operatorname{grad} \gamma) R_{\pm}(\alpha) = 2\alpha \operatorname{grad} R_{\pm}(\alpha + 2);$
- (3)  $\square R_{\pm}(\alpha + 2) = R_{\pm}(\alpha).$

Moreover, the map

$$\begin{aligned} \mathbb{X}_n &\rightarrow \mathcal{D}'(\mathbb{M}^n) \\ \alpha &\mapsto R_{\pm}(\alpha) \end{aligned}$$

(where  $\mathbb{X}_n := \{\alpha \in \mathbb{C} \mid \operatorname{Re} \alpha > n\}$ ) extends uniquely the whole complex plane as a holomorphic family of distributions, i.e. for each test-function  $\varphi \in \mathcal{D}(\mathbb{M}^n)$ , the function  $\alpha \mapsto (R_{\pm}(\alpha), \varphi)$  is holomorphic.

**Proof.** To prove (1), we evaluate  $\gamma R_{\pm}(\alpha)$  inside  $J_{\pm}(0)$ , because both sides of the equation vanish outside. By definition one has

$$\gamma R_{\pm}(\alpha) = C(\alpha, n) \gamma(x)^{\frac{\alpha+2-n}{2}} = \frac{C(\alpha, n)}{C(\alpha+2, n)} R_{\pm}(\alpha+2),$$

and, in virtue of the fact that  $z\Gamma(z-1) = \Gamma(z)$ ,

$$\begin{aligned} \frac{C(\alpha, n)}{C(\alpha+2, n)} &= \frac{2^{1-\alpha} \pi^{\frac{2-n}{n}}}{(\frac{\alpha}{2}-1)! (\frac{\alpha-n}{2})!} \frac{(\frac{\alpha+2}{2}-1)! (\frac{\alpha+2-n}{2})!}{2^{1-\alpha-2} \pi^{\frac{2-n}{n}}} = \\ &= 4 \frac{\alpha}{2} \frac{\alpha+2-n}{2} = \alpha(\alpha-n+2). \end{aligned}$$

For the second identity we evaluate  $\partial_i \gamma \cdot R_{\pm}(\alpha)$ . In view of Remark 2.5.2,  $R_{\pm}(\alpha+2) \in C^1(\mathbb{M}^n)$  For any  $\varphi$  integrating by parts yields:

$$\begin{aligned} \partial_i \gamma \cdot (R_{\pm}(\alpha), \varphi) &= C(\alpha, n) \int_{J_{\pm}} \gamma(x)^{\frac{\alpha-n}{2}} \partial_i \gamma(x) \varphi(x) \, dx \\ &= \frac{2C(\alpha, n)}{\alpha+2-n} \int_{J_{\pm}} \partial_i (\gamma(x))^{\frac{\alpha-n+2}{2}} \varphi(x) \, dx \\ &= -2C(\alpha+2, n) \int_{J_{\pm}} \gamma(x)^{\frac{\alpha-n+2}{2}} \partial_i \varphi(x) \, dx \\ &= -2\alpha (R_{\pm}(\alpha+2), \partial_i \varphi) \\ &= 2\alpha (\partial_i R_{\pm}(\alpha), \varphi). \end{aligned}$$

 FIGURE 2.7: Iterative extension of  $R_{\pm}(\alpha)$  on  $\mathbb{C}$ .

To prove the third formula, from (2) we have

$$\begin{aligned}
 \partial_i^2 R_{\pm}(\alpha + 2) &= \partial_i \left( \frac{1}{2\alpha} \partial_i \gamma \cdot R_{\pm}(\alpha) \right) \\
 &= \frac{1}{2\alpha} \partial_i^2 \gamma \cdot R_{\pm}(\alpha) + \frac{1}{4\alpha(\alpha - 2)} (\partial_i \gamma)^2 \frac{(\alpha - 2)(\alpha - n)}{\gamma} \cdot R_{\pm}(\alpha) \\
 &= \left( \frac{1}{2\alpha} \partial_i^2 \gamma + \frac{\alpha - n}{4\alpha} \cdot \frac{(\partial_i \gamma)^2}{\gamma} \right) \cdot R_{\pm}(\alpha).
 \end{aligned}$$

Applying  $\square$  we find

$$\square R_{\pm}(\alpha + 2) = \left( \frac{n}{\alpha} + \frac{\alpha - n}{4\alpha} \cdot \frac{4\gamma}{\gamma} \right) R_{\pm}(\alpha) = R_{\pm}(\alpha),$$

as claimed.

The last identity allows us to extend  $R_{\pm}(\alpha)$  for every  $\alpha \in \mathbb{C}$ . For  $\text{Re } \alpha > n - 2$  we set

$$\tilde{R}_{\pm}(\alpha) := \square R_{\pm}(\alpha + 2),$$

and the extension is holomorphic on  $\mathbb{X}_{n-2}$ . Now, proceeding by induction over  $n$  one can extend the function over the whole complex plane.  $\blacksquare$

**2.5.4 Definition.** *The distributions  $R_+(\alpha)$  and  $R_-(\alpha)$  defined in the last proposition are called respectively the **retarded** and **advanced** Riesz distributions for the parameter  $\alpha \in \mathbb{C}$ .*

The Riesz distributions do not have an immediate explicit formula, but next lemma shows a more comfortable way to evaluate them when the test-function

has a particular form. For the proof of this lemma, we remind to [3, Lem 1.3.30].

**2.5.5 Lemma.** Denote  $x = (t, \mathbf{x})$ , with  $\mathbf{x} \in \mathbb{R}^{n-1}$ . Let  $f \in \mathcal{D}(\mathbb{R})$  and let  $\psi \in \mathcal{D}(\mathbb{R}^{n-1})$  be such that  $\varphi(x) := f(t)\psi(\mathbf{x}) \in \mathcal{D}(\mathbb{M}^n)$  and  $\varphi(x) = f(t)$  on  $J_+(0)$ . If  $\operatorname{Re} \alpha > 1$  it holds

$$(R_{\pm}(\alpha), \varphi) = \frac{1}{(\alpha - 1)!} \int_0^{+\infty} t^{\alpha-1} f(t) dt.$$

To link Riesz distributions to fundamental solutions the following facts are noteworthy.

**2.5.6 Proposition.** The Riesz distributions satisfy

- (1) for any  $\alpha \in \mathbb{C}$ ,  $\operatorname{supp} R_{\pm}(\alpha) \subset J_{\pm}(0)$
- (2)  $R_{\pm}(0) = \delta_0$
- (3)  $\square R_{\pm}(2) = \delta_0$ , in particular  $R_+(2)$  and  $R_-(2)$  are respectively a **retarded** and an **advanced** fundamental solution for  $\square$  at 0.

**Proof.** The first assertion descends from the definition of Riesz distributions. To prove (2) fix  $K \subset \mathbb{M}^n$  compact subset. Let  $\sigma_K \in \mathcal{D}(\mathbb{M}^n)$  such that  $\sigma_K|_K = 1$ . For any  $\varphi \in \mathcal{D}(\mathbb{M}^n)$  with  $\operatorname{supp} \varphi \subset K$  one finds suitable smooth functions  $\varphi_j$  such that

$$\varphi(x) = \varphi(0) + \sum_{j=1}^n x^j \varphi_j(x),$$

then it holds

$$\begin{aligned} (R_{\pm}(0), \varphi) &= (R_{\pm}(0), \sigma_K \varphi) \\ &= \left( R_{\pm}(0), \varphi(0) + \sum_{j=1}^n x^j \varphi_j(x) \right) \\ &= \varphi(0) \overbrace{(R_{\pm}(0), \sigma_K)}^{=: c_K} + \sum_{j=1}^n \left( \overbrace{x^j R_{\pm}(0)}^{=: 0}, \sigma_K \varphi_j \right) \\ &= c_K \varphi(0), \end{aligned}$$

where  $x^j R_\pm(0)$  vanishes because of Equation (1) in Proposition 2.5.3 one can show that  $c_K$  does not depend on the choice of  $K$  since for  $K' \supset K$  and  $\text{supp } \varphi \subset K \subset K'$ ,

$$c'_K \varphi(0) = (R_+(0), \varphi) = c_K \varphi(0).$$

It descends  $c_K = c'_K =: c$ . To show  $c = 1$ , concentrating on the case of a retarded distribution, using test-functions as in Lemma 2.5.5,

$$\begin{aligned} c \cdot \varphi(0) &= (R_+(0), \varphi) \\ &= (\square R_+(2), \varphi) = (R_+(2), \square \varphi) \\ &= \int_0^{+\infty} t f''(t) dt = - \int_0^{+\infty} f'(t) dt \\ &= f(0) = \varphi(0), \end{aligned}$$

which concludes the proof.

The third assertion is obtained considering (1) and making use of Equation (3) in Proposition 2.5.3. ■

**2.5.7 Remark.** We will prove in Chapter 3 that the retarded and the advanced fundamental solutions are **unique**. Hence, we have

$$G_\pm = R_\pm(2).$$

**2.5.8 Remark.** As one expects, if  $\alpha \in \mathbb{R}$ , then  $(R_\pm(\alpha), \varphi)$  is real for any  $\varphi \in \mathcal{D}(\mathbb{M}^n, \mathbb{R})$  i.e.  $R_\pm(\alpha)$  is a real-valued distribution.

We are now ready to prove **Huygens' principle**, that we already mentioned before. One can restate it as follows.

**2.5.9 Theorem (Huygens' principle).** *If  $n \geq 4$  is even,  $\text{supp } G_\pm = C_\pm(0)$ . If  $n \geq 3$  is odd,  $\text{supp } G_\pm = J_\pm(0)$ .*

To prove it we work with Riesz distributions and we need the following lemma<sup>3</sup>.

**2.5.10 Lemma.** *The following holds:*

- (1) *for every  $\alpha \in \mathbb{C} \setminus (\{0, -2, -4, \dots\} \cup \{n-2, n-4, \dots\})$  we have  $\text{supp } R_\pm(\alpha) = J_\pm(0)$ ;*
- (2) *for  $n \geq 3$  and  $\alpha = n-2, n-4, \dots, 1$  if  $n$  is odd or  $\alpha = n-2, n-4, \dots, 2$  if  $n$  is even, we have  $\text{supp } R_\pm(\alpha) = C_\pm(0)$ .*

---

<sup>3</sup>see [3, Prop. 1.3.31]

**Proof of Theorem 2.5.9.** The fundamental solutions are  $G^\pm = R_\pm(2)$ , so  $\alpha = 2$ . Since  $2 = (n-2) + (4-n)$ , if  $n \geq 4$  and  $n$  is even,  $2 \in \{n-2, n-4, \dots\}$ ; conversely, if  $n$  is odd 2 is not in  $\{n-2, n-4, \dots, 1\}$ . So the theorem follows from the last lemma.  $\blacksquare$

## 2.6 General solution and Cauchy problem

We found the fundamental solution for the d'Alembert wave operator for the point  $x_0 = 0$ . To find the generic solution at a point  $y \in \mathbb{M}^n$ , as we have seen in Proposition 2.2.2, it suffices to write

$$G_y^+(x) = T_y G_+ = G_+(x - y).$$

Hence, to find the retarded solution  $u_+(x)$  to the wave equation  $\square u = \psi$ , where  $\psi$  is a distribution, we simply evaluate the convolution  $G_+ * \psi$ . The general solution is obtained by adding the solutions of the homogeneous equation as in Formula (2.6).

Now we discuss the uniqueness of the distributional solution and for its regularity we refer to Proposition 2.2.2.

To begin, we shall prove the following<sup>4</sup>

**2.6.1 Theorem.** *Let  $\psi \in \mathcal{D}'(\mathbb{M}^n)$  such that  $\psi(t, \mathbf{x}) = 0$  if  $t < 0$ . Then  $\psi$  and  $G_+$  can be convoluted and  $u_+ = G_+ * \psi$  is the unique solution to the wave equation with source  $\psi$  such that  $u_+(t, \mathbf{x}) = 0$  for  $t < 0$ .*

**Proof.** At fixed  $x$ , the distribution  $G_+(x - y)\psi(y)$  has compact support in the variable  $y$ , so  $G_+$  and  $\psi$  can be convoluted. Since  $\text{supp } G_+ \subset J_+(0)$ ,  $u_+ = 0$  for  $t < 0$ .

The solution is unique because if there were another  $u$  solving the equation and satisfying the requested conditions, then  $\phi := u_+ - u$  would be a solution to the homogeneous equation, i.e.  $\square \phi = 0$ , and  $\phi$  could be convoluted with  $G_+$ :

$$\phi = \phi * \delta = \phi * \square G_+ = \square \phi * G_+ = 0,$$

hence  $u = u_+$ .  $\blacksquare$

Remaining in the Minkowski case, since  $\mathbb{M}^n$  is a globally hyperbolic manifold, we can find smooth Cauchy hypersurfaces, where we can assign initial values.

---

<sup>4</sup>see [10, Sec. 5.3]

Physically, it is clear why these can only be specified on a spacelike surface. A wave cannot travel from one point of the initial value surface to another and change the initial conditions.

**2.6.2 Definition.** Let  $S$  be a smooth Cauchy hypersurface of  $\mathbb{M}^n$  with a timelike oriented unit normal vector field  $n : S \rightarrow T\mathbb{M}^n$ .

Given a triple  $(\psi, u_0, u_1) \in \mathcal{D}(\mathbb{M}^n) \oplus \mathcal{D}(S) \oplus \mathcal{D}(S)$ , we call a **classical Cauchy problem** for  $\square$  on  $S$  the system of equations

$$\begin{cases} \square u = \psi \\ u|_S = u_0 \\ \partial_n u|_S = u_1. \end{cases} \quad (2.15)$$

In case the triple is taken in  $\mathcal{D}'(\mathbb{M}^n) \oplus \mathcal{D}'(S) \oplus \mathcal{D}'(S)$ , i.e. the data are distributions, the problem is called **generalized Cauchy problem**.

For simplicity, we concentrate on the case where  $S$  is the hyperplane

$$S_0 := \{(t, \mathbf{x}) \in \mathbb{M} \mid t = 0\},$$

and  $\partial_n = \partial_t$ . The general case will be addressed later in Section 3.3, when we will discuss of Cauchy problem on manifolds. To solve the initial value problem, we start with a lemma

**2.6.3 Lemma.** Suppose  $u$  is a solution for the Cauchy problem on  $S_0$ . If we set

$$\begin{aligned} \tilde{u}(t, \mathbf{x}) &:= \begin{cases} u(t, \mathbf{x}) & \text{if } t > 0 \\ 0 & \text{otherwise,} \end{cases} \\ \tilde{\psi}(t, \mathbf{x}) &:= \begin{cases} \psi(t, \mathbf{x}) & \text{if } t > 0 \\ 0 & \text{otherwise,} \end{cases} \end{aligned}$$

it holds

$$\square \tilde{u}(t, \mathbf{x}) = \tilde{\psi}(t, \mathbf{x}) + u_0(\mathbf{x})\delta'(t) + u_1(\mathbf{x})\delta(t). \quad (2.16)$$

**Proof.** Let  $\varphi \in \mathcal{D}'(\mathbb{M}^n)$ , then

$$(\square \tilde{u}, \varphi) = (\tilde{u}, \square \varphi) = \int_0^\infty dt \int u \square \varphi \, d\mathbf{x} =$$

integrating by parts in the time variable

$$\begin{aligned} &= \int_0^\infty dt \int \square u \varphi \, d\mathbf{x} + \int \partial_t u(0, \mathbf{x}) \varphi(0, \mathbf{x}) - u(0, \mathbf{x}) \partial_t \varphi(0, \mathbf{x}) \, d\mathbf{x} = \\ &= \int \tilde{\psi} + u_1 \delta(t) + u_0 \delta'(t) \, dt \, d\mathbf{x}. \end{aligned}$$

■

**2.6.4 Theorem** <sup>(5)</sup>. *If  $u_\pm \in C^\infty(\mathbb{M}^n)$  solves the Cauchy problem on  $S_0$  and  $\text{supp } u_\pm \subset J_\pm(K)$ , where  $K := \text{supp } u_0 \cup \text{supp } u_1 \cup \text{supp } \psi$ , then it holds*

$$u_\pm = G_\pm * (\psi + u_0 \otimes \delta' + u_1 \otimes \delta). \quad (2.17)$$

This leads to the following Corollary, that will be addressed in the general setting in Section 3.3.

**2.6.5 Corollary.** *If  $u \in C^\infty(\mathbb{M}^n)$  solves the Cauchy problem on  $S_0$  with  $Pu = 0$  (i.e.  $\psi = 0$ ), then*

$$\text{supp } u \subset J_+(K) \cup J_-(K),$$

where  $K := \text{supp } u_0 \cup \text{supp } u_1$ , and a solution is given by

$$u = G * (u_0 \otimes \delta' + u_1 \otimes \delta) \quad (2.18)$$

for all  $\varphi \in \mathcal{D}(\mathbb{M}^n)$ , where  $G = G_+ - G_-$ .

Now follows the general result on  $S_0$ .

**2.6.6 Theorem.** *For each  $(\psi, u_0, u_1) \in \mathcal{D}(\mathbb{M}^n) \oplus \mathcal{D}(S_0) \oplus \mathcal{D}(S_0)$ , there exists a unique solution  $u$  to the Cauchy problem on  $S_0$ . Furthermore  $\text{supp } u \subset J_+(K) \cup J_-(K)$ , where  $K := \text{supp } u_0 \cup \text{supp } u_1 \cup \text{supp } \psi$ .*

**Proof.** We will only prove the existence. To build it with initial values  $u_0, u_1$  we need the sum of a particular solution and the solution for the homogeneous equation.

We start by noting that a particular solution of  $\square \tilde{\phi} = \psi$  induces initial values on  $S_0$  given by  $\tilde{u}_0(\mathbf{x}) = G_+ * \psi(0, \mathbf{x})$  and  $\tilde{u}_1(\mathbf{x}) = \partial_t G_+ * \psi(0, \mathbf{x})$ . Hence, for

---

<sup>5</sup>see [10, Th. 5.3.2]

the homogeneous equation with initial values  $u_0, u_1$ , we apply Corollary 2.6.5 with initial values  $u_0 - \tilde{u}_0$  and  $u_1 - \tilde{u}_0$  and find  $\hat{\phi}$ .  
The general solution will be  $\phi = \hat{\phi} + \tilde{\phi}$ . ■

The solution, if we concentrate on the classical Cauchy problem, is smooth (Proposition 2.2.2) and depends continuously on the initial data, hence the map that gives the solution  $u$  can be seen as a **linear continuous operator**

$$\begin{aligned} \mathcal{D}(\mathbb{M}^n) \oplus \mathcal{D}(S) \oplus \mathcal{D}(S) &\rightarrow C^\infty(\mathbb{M}^n) \\ (\psi, u_0, u_1) &\mapsto u. \end{aligned}$$

---

In this chapter, the Riesz distributions will be transported on suitable domains of Lorentzian manifolds to construct local fundamental solutions and it will be discussed the local and global solvability of the Cauchy problem.

At first we will present some examples of generalized d'Alembert operators on some globally hyperbolic manifolds interesting for their physical applications, to show why we are interested in solving wave-like equations on manifolds and why we will follow this approach. In fact, in this setting, the methods of Fourier transform are unmanageable, but Riesz distributions are far more generalizable.

We will start by pulling back the Riesz distributions from the tangent space to an open neighborhood of a fixed point in a Lorentzian manifold using the exponential map and we will discuss the properties that still hold. We will see that none of the pulled back Riesz distributions defines a fundamental solution to any wave-like operator, but we can combine them in a certain way to obtain approximate fundamental solutions.

Precisely, we will make a formal ansatz: we will write a formal solution as a series of Riesz distributions  $\mathcal{R}_\pm$  with functions as coefficients to be determined. Requiring  $\mathcal{R}_\pm$  to be a fundamental solution, we will find recursive relations for the coefficients that will depend on the particular wave-like operator we are trying to solve, but that can be found in general. In this way a formal fundamental solution will be constructed as a series for which the higher terms must be cut in a precise way in order to get a true solution. We will show that it is always possible to find such a regularization  $\tilde{\mathcal{R}}_\pm$  and make the formal series

converge. Unfortunately the formal series does not immediately converge to a fundamental solution, hence we will have to get rid of the difference between the true and the approximate fundamental solution, denoted by  $K_{\pm}$ , inverting the integral kernel  $\mathcal{K}_{\pm}$  induced by  $K_{\pm}$ . We will show that this can be done only locally.

This considerations will lead to solutions of local Cauchy problems and we will show the regularity of such a solution with smooth initial data. Then we will generalize the results on *globally hyperbolic* manifolds (see Definition 1.2.21). This result will be used to show that global fundamental solutions exist in this case. All the solution will have support properties that respect the causality principle: in fact the support of any solution is contained in the union of causal future and causal past of the support of its initial data.

### 3.1 Examples of generalized d'Alembert operators

We recall from Section 1.3 that a **generalized d'Alembert** operator on a manifold  $M$  is given in local coordinates by

$$P = -g^{ij}(x) \frac{\partial^2}{\partial x^i \partial x^j} + a^j(x) \frac{\partial}{\partial x^j} + b(x), \quad (3.1)$$

where  $g^{ij}$  is the metric and  $a^j, b$  are smooth function.

We now show the form of  $P$ , assuming for simplicity that  $a^j$  and  $b$  vanish, on manifolds of physical interest such as Minkowski spacetime  $\mathbb{M}^n$ , cosmological spacetimes or Schwarzschild spacetimes, defined in Example 1.2.24.

In the first case,  $g_{\mathbb{M}^n} = \eta$ , hence the generalized d'Alembert operator coincide with the d'Alembert wave operator  $\square$ .

For cosmological spacetimes  $g_c = -dt^2 + f^2(t) b_t$ , with  $f$  positive function and  $b_t$  a Riemannian metric. In case  $(b_t)_{ij} = \delta_{ij} dx_i dx_j$  is the euclidean metric,  $g_c = -dt^2 + f^2(t) \sum_i dx_i^2$  and

$$P_c = \frac{\partial^2}{\partial t^2} - \frac{1}{f^2(t)} \sum_{i=1}^{n-1} \frac{\partial^2}{\partial x_i^2}.$$

In Schwarzschild spacetime

$$g_s = -h(r) dt^2 + \frac{1}{h(r)} dr^2 + r^2 g_{S^2},$$

where  $h(r) = 1 - \frac{2m}{r}$  while  $g_{S^2} = r^2 d\vartheta^2 + r^2 \sin^2 \vartheta d\varphi^2$ . Hence the generalized d'Alembert operator reads

$$P_s = \frac{1}{h(r)} \frac{\partial^2}{\partial t^2} - h(r) \frac{\partial^2}{\partial r^2} - \frac{1}{r^2} \frac{\partial^2}{\partial \vartheta^2} - \frac{1}{r^2 \sin^2 \vartheta} \frac{\partial^2}{\partial \varphi^2}.$$

The Fourier transform techniques rely on the translational symmetry possessed by Minkowski spacetime. Therefore, for a generic curved background, such as Schwarzschild or cosmological spacetimes, in which there is not such symmetry, the Fourier method is not well-suited. Moreover, the form assumed by the operator  $P$  in the examples we covered does not possess any explicit symmetry.

## 3.2 Local fundamental solutions

In Section 2.5 Riesz distributions have been defined on the tangent spaces of an arbitrary point of a Lorentzian manifold, following [5]. We show how to extend Riesz distributions small open subsets of the Lorentzian manifold. The step from the tangent space to the manifold will be provided by the exponential map.

**3.2.1 Definition.** *Let  $\Omega \subset M$  be a geodesically starshaped open subset with respect to a point  $x \in M$ . For  $\alpha \in \mathbb{C}$  and for every  $\varphi \in \mathcal{D}(\Omega M)$  we call Riesz distribution*

$$(R_{\pm}^{\Omega}(\alpha, x), \varphi) := (R_{\pm}(\alpha), (\mu_x \varphi) \circ \exp_x),$$

where  $\exp_x : \exp_x^{-1}(\Omega) \subset T_x \Omega \rightarrow \Omega$  is the exponential map at  $x$  while  $\mu_x : \Omega \rightarrow \mathbb{R}$  is the volume form defined as in equation (1.4).

We call  $R_{+}^{\Omega}(\alpha, x)$  and  $R_{-}^{\Omega}(\alpha, x)$  respectively the **retarded** and the **advanced** Riesz distributions on  $\Omega$  for  $\alpha \in \mathbb{C}$ .

Note that, since  $\text{supp}(\mu_x \varphi) \circ \exp_x \subset \Omega$ , it can be regarded as a test-function on  $T_x \Omega$  for the Riesz distribution.

Distributions on a geodesically starshaped domain maintain some of the properties of the Minkowski counterpart, namely the ones expressed in Proposition 2.5.3 and in Proposition 2.5.6, even if with some slight differences.

**3.2.2 Theorem.** *Let  $\Omega \subset M$  be a geodesically starshaped open subset with respect to a point  $x \in M$ . For all  $\alpha \in \mathbb{C}$  it holds*

(1) If  $\operatorname{Re} \alpha > n$ , then

$$R_{\pm}^{\Omega}(\alpha, x) := \begin{cases} C(\alpha, n) \Gamma_x^{\frac{\alpha-n}{2}} & \text{on } J_{\pm}^{\Omega}(x) \\ 0 & \text{elsewhere,} \end{cases} \quad (3.2)$$

where  $C(\alpha, n)$  are defined in Definition 2.5.1, while  $\Gamma_x$  is defined in Definition 1.2.17.

(2)  $\operatorname{supp} R_{\pm}^{\Omega}(\alpha, x) \subset J_{\pm}(x)$ .

(3) For every  $\varphi \in \mathcal{D}(\Omega)$  the map  $\alpha \mapsto (R_{\pm}^{\Omega}(\alpha, x), \varphi)$  is holomorphic on  $\mathbb{C}$ .

(4)  $\Gamma_x R_{\pm}^{\Omega}(\alpha, x) = \alpha(\alpha - n + 2) R_{\pm}^{\Omega}(\alpha + 2, x)$ .

(5)  $\operatorname{grad} \Gamma_x \cdot R_{\pm}^{\Omega}(\alpha, x) = 2\alpha \operatorname{grad} R_{\pm}^{\Omega}(\alpha + 2, x)$ .

(6)  $R_{\pm}^{\Omega}(0, x) = \delta_x$ .

(7)  $\square R_{\pm}^{\Omega}(\alpha + 2, x) = \left( \frac{\square \Gamma_x - 2n}{2\alpha} + 1 \right) R_{\pm}^{\Omega}(\alpha, x)$  for all  $\alpha \neq 0$ .

To prove the properties of Theorem 3.2.2 we need a Lemma which helps dealing with  $\Gamma_x$ , the function that takes the place of  $\gamma$  in the formulas for the Riesz distributions on a manifold.

**3.2.3 Lemma.** *Let  $\Omega \subset M$  be an open and geodesically starshaped subset with respect to  $x \in M$ . Then it holds that*

(1)  $\langle \operatorname{grad} \Gamma_x, \operatorname{grad} \Gamma_x \rangle = -4\Gamma_x$ ;

(2)  $\square \Gamma_x = 2n - \langle \operatorname{grad} \Gamma_x, \operatorname{grad} \ln(\mu_x) \rangle$ .

**Proof.** We prove (1) in Minkowski spacetime, where we can identify  $\Gamma$  with the geodesic distance  $\gamma = (x^1)^2 - (x^2)^2 - \dots - (x^n)^2$ . In other words

$$\operatorname{grad} \gamma = \eta^{ij} \frac{\partial \gamma}{\partial x^i} \frac{\partial}{\partial x^j} = -2x^i \frac{\partial}{\partial x^i}. \quad (3.3)$$

Hence the first formula follows from direct computation:

$$\begin{aligned} \langle \operatorname{grad} \gamma, \operatorname{grad} \gamma \rangle &= \left\langle -2x^i \frac{\partial}{\partial x^i}, -2x^i \frac{\partial}{\partial x^i} \right\rangle \\ &= 4((x^1)^2 - (x^2)^2 - \dots - (x^n)^2) \\ &= -4\gamma. \end{aligned}$$

To prove (2) we notice that Leibniz rule for the divergence operator reads

$$\operatorname{div}(fZ) = f \operatorname{div} Z + \langle \operatorname{grad} f, Z \rangle, \quad (3.4)$$

for any vector field  $Z$  and for any smooth function  $f$  on  $M$ . Hence, equation (3.3) generalizes in normal coordinates as

$$\operatorname{grad} \Gamma_x = -2x^j \frac{\partial}{\partial x^j}.$$

Using (3.4) with  $f = \mu_x^{-1}$  and  $Z = \operatorname{grad} \Gamma_x$ , we obtain

$$\operatorname{div}(\mu_x^{-1} \operatorname{grad} \Gamma_x) = \mu_x^{-1} \operatorname{div} \operatorname{grad} \Gamma_x + \langle \operatorname{grad} \mu_x^{-1}, \operatorname{grad} \Gamma_x \rangle.$$

Since

$$\begin{aligned} \square \Gamma_x &= -\operatorname{div} \operatorname{grad} \Gamma_x \\ &= \mu_x \langle \operatorname{grad} \mu_x^{-1}, \operatorname{grad} \Gamma_x \rangle - \mu_x \operatorname{div}(\mu_x^{-1} \operatorname{grad} \Gamma_x) \\ &= -\langle \operatorname{grad} \ln \mu_x, \operatorname{grad} \Gamma_x \rangle - \mu_x \operatorname{div}(\mu_x^{-1} \operatorname{grad} \Gamma_x), \end{aligned}$$

it remains to be shown that  $\mu_x \operatorname{div}(\mu_x^{-1} \operatorname{grad} \Gamma_x) = -2n$ . Using the definition of divergence and equation (1.6),

$$\mu_x \operatorname{div}(\mu_x \operatorname{grad} \Gamma_x) = \frac{\partial}{\partial x^j} (\operatorname{grad} \Gamma_x)^j = -2 \frac{\partial}{\partial x^j} x^j = -2n.$$

For a complete proof, we remind to [2, Lem 1.3.19] ■

**Proof of Theorem (3.2.2).** Let  $\operatorname{Re} \alpha > n$ ,  $\varphi \in \mathcal{D}(\Omega)$  and let us denote with  $X$  the tangent vectors in  $T_x \Omega$ . Then from Definition 3.2.1,

$$\begin{aligned} (R_{\pm}^{\Omega}(\alpha, x), \varphi) &= (R_{\pm}(\alpha), (\mu_x \varphi) \circ \exp_x) \\ &= C(\alpha, n) \int_{J_{\pm}(0)} \gamma^{\frac{\alpha-n}{2}}(X) \mu_x \varphi(\exp_x(X)) \, dX \\ &= C(\alpha, n) \int_{J_{\pm}^{\Omega}(x)} \Gamma_x^{\frac{\alpha-n}{2}} \varphi(x) \, d\mu. \end{aligned}$$

Assertions (2) and (3) follow directly from the corresponding properties of the Riesz distributions on Minkowski spacetime.

By (1), equation (4) holds when  $\operatorname{Re} \alpha > n$  on account of the corresponding counterpart in the Minkowski case. By analytic extension of the distribution,

it must hold in the whole complex plain.

To prove (5), we compute for  $\operatorname{Re} \alpha > n$

$$\begin{aligned} 2\alpha \operatorname{grad} R_{\pm}^{\Omega}(\alpha + 2, x) &= 2\alpha C(\alpha + 2, n) \operatorname{grad} \Gamma_x^{\frac{\alpha+2-n}{2}} \\ &= 2\alpha C(\alpha + 2, n) \frac{\alpha + 2 - n}{2} \Gamma_x^{\frac{\alpha-n}{2}} \operatorname{grad} \Gamma_x \\ &= R_{\pm}^{\Omega}(\alpha, x) \operatorname{grad} \Gamma_x. \end{aligned}$$

and again we extend it for any complex  $\alpha$  through analyticity.

To prove (6) let  $\varphi \in \mathcal{D}(\Omega)$ . Then,

$$\begin{aligned} (R_{\pm}^{\Omega}(0, x), \varphi) &= (R_{\pm}(0), (\mu_x \varphi) \circ \exp_x) \\ &= (\delta_0, (\mu_x \varphi) \circ \exp_x) \\ &= ((\mu_x \varphi) \circ \exp_x)(0) = \varphi(x) \\ &= (\delta_x, \varphi), \end{aligned}$$

where we used equation (2) in Proposition 2.5.6. To prove (7) we take  $\alpha \in \mathbb{C}$  such that  $\operatorname{Re} \alpha > n + 2$  so that  $R_{\pm}^{\Omega}(\alpha + 2, x)$  is  $C^2$ . by the means of analytic extension of the distribution, the relation must hold for any  $\alpha \in \mathbb{C}$ .

$$\begin{aligned} \square R_{\pm}^{\Omega}(\alpha + 2, x) &= -\operatorname{div} \operatorname{grad} R_{\pm}^{\Omega}(\alpha + 2, x) \\ &= -\frac{1}{2\alpha} \operatorname{div} (R_{\pm}^{\Omega}(\alpha, x) \cdot \operatorname{grad} \Gamma_x) \\ &= \frac{1}{2\alpha} \square \Gamma_x R_{\pm}^{\Omega}(\alpha, x) - \frac{1}{2\alpha} \langle \operatorname{grad} \Gamma_x, \operatorname{grad} R_{\pm}^{\Omega}(\alpha, x) \rangle \\ &= \frac{1}{2\alpha} \square \Gamma_x R_{\pm}^{\Omega}(\alpha, x) - \frac{R_{\pm}^{\Omega}(\alpha - 2, x)}{2\alpha \cdot 2(\alpha - 2)} \langle \operatorname{grad} \Gamma_x, \operatorname{grad} \Gamma_x \rangle, \end{aligned}$$

and making use of equation (1) in Lemma (3.2.3) we have

$$\begin{aligned} &= \frac{1}{2\alpha} \square \Gamma_x \cdot R_{\pm}^{\Omega}(\alpha, x) + \frac{1}{\alpha(\alpha - 2)} \Gamma_x R_{\pm}^{\Omega}(\alpha - 2, x) \\ &= \frac{1}{2\alpha} \square \Gamma_x \cdot R_{\pm}^{\Omega}(\alpha, x) + \frac{(\alpha - 2)(\alpha - n)}{\alpha(\alpha - 2)} R_{\pm}^{\Omega}(\alpha, x) \\ &= \left( \frac{\square \Gamma_x - 2n}{2\alpha} + 1 \right) R_{\pm}^{\Omega}(\alpha, x). \end{aligned}$$

■

### 3.2.1 Formal ansatz

One may think, in analogy with the Minkowski scenario, that properties (2) and (6) expressed in the Theorem 3.2.2 make the Riesz distribution  $R_{\pm}^{\Omega}(2, x)$  a good candidate to be a fundamental solution for  $\square$  at  $x$ . The situation is far more complicated: in fact, one can not compute  $\square R_{\pm}^{\Omega}(\alpha + 2, x)$  for  $\alpha = 0$  unless  $\square \Gamma_x - 2n$  vanishes identically, which in general is not the case. It turns out that  $R_{\pm}^{\Omega}(2, x)$  does not suffice to construct fundamental solutions and to this end also  $R_{\pm}^{\Omega}(2k + 2, x)$  for  $k \geq 1$  are needed.

Let  $\Omega$  be a geodesically starshaped open subset with respect to a given  $x \in M$  so that the Riesz distributions are well defined. We look for fundamental solutions  $\mathcal{R}_{\pm}$  for a generalized d'Alembert operator  $P$ , defined in equation (3.1). We want to combine them in order to have a formal series, with unknown coefficients, and make it converge under suitable conditions. We make a formal ansatz following [5] and [3, Sec 2.2.1]: we look for fundamental solutions for  $P$  of the form

$$\mathcal{R}_{\pm}(x) = \sum_{k=0}^{\infty} V_x^k \cdot R_{\pm}^{\Omega}(2k + 2, x), \quad (3.5)$$

where for each  $k$ ,  $V_x^k$  is a smooth function yet to be found.

The series above is only formal, but applying  $P$  term to term and requiring  $\mathcal{R}_{\pm}(x)$  to be a fundamental solution one has

$$P\mathcal{R}_{\pm}(x) = \sum_{k=0}^{\infty} P \left( V_x^k \cdot R_{\pm}^{\Omega}(2k + 2, x) \right) = \delta_x.$$

Hence, one can translate the condition of  $\mathcal{R}_{\pm}(x)$  being a fundamental solution at  $x$  into conditions on the  $V_x^k$ . To do this we need a lemma<sup>1</sup>.

**3.2.4 Lemma.** *Let  $P$  be a generalized d'Alembert operator as in equation (3.1) and let  $f, g \in C^{\infty}(\Omega)$ . Then it holds*

$$P(fg) = \square f g - 2\partial_{\text{grad } f} g + P(g) f.$$

---

<sup>1</sup>see [3, Lem 2.1.9]

Using the last lemma with  $f = R_{\pm}^{\Omega}(2k+2, x)$ ,  $g = V_x^k$  and properties (4), (5) and (7) in Theorem 3.2.2 we compute

$$\begin{aligned} R_{\pm}^{\Omega}(0, x) &= \sum_{k=0}^{\infty} P \left( V_x^k \cdot R_{\pm}^{\Omega}(2k+2, x) \right) = \\ &= \sum_{k=0}^{\infty} \left\{ V_x^k \cdot \square R_{\pm}^{\Omega}(2+2k, x) - 2\partial_{\text{grad } R_{\pm}^{\Omega}(2+2k, x)} V_x^k + P V_x^k \cdot R_{\pm}^{\Omega}(2k+2, x) \right\} \\ &= V_x^0 \cdot \square R_{\pm}^{\Omega}(2, x) - 2\partial_{\text{grad } R_{\pm}^{\Omega}(2, x)} V_x^0 + \\ &+ \sum_{k=1}^{\infty} \frac{1}{2k} \left\{ V_x^k \left( \frac{1}{2} \square \Gamma_x - n + 2k \right) - \partial_{\text{grad } \Gamma_x} V_x^k + 2k P V_x^{k-1} \right\} R_{\pm}^{\Omega}(2k, x). \end{aligned}$$

Identifying the coefficients in front of  $R_{\pm}^{\Omega}(2k, x)$  we get the conditions

$$\text{for } k = 0 \quad 2\partial_{\text{grad } R_{\pm}^{\Omega}(2, x)} V_x^0 - \square R_{\pm}^{\Omega}(2, x) V_x^0 + R_{\pm}^{\Omega}(0, x) = 0, \quad (3.6a)$$

$$\text{for } k \geq 1 \quad \partial_{\text{grad } \Gamma_x} V_x^k - \left( \frac{1}{2} \square \Gamma_x - n + 2k \right) V_x^k = 2k P V_x^{k-1}. \quad (3.6b)$$

For consistency with the Minkowski case, between the functions that solve (3.6a), one chooses  $V_x^0(x) \equiv 1$ . To see why, one has to recall that if  $P = \square$  in Minkowski,  $R_{\pm}(2)$  are fundamental solutions (see Proposition 2.5.6), hence the correspondent series (3.5) has to stop at  $k = 0$  and the coefficient  $V_x^0(x)$  has to be unitary.

**3.2.5 Definition.** Let  $\Omega \subset M$  be a geodesically starshaped open subset with respect to  $x \in M$  and  $P$  a generalized d'Alembert operator as in equation (3.1). A sequence of **Hadamard coefficients** for  $P$  at  $x \in \Omega$  is a sequence  $\{V_x^k\}_{k \in \mathbb{N}}$  of  $C^{\infty}(\Omega)$  which fulfills equation (3.6b) with  $V_x^0(x) = 1$  for all  $x \in \Omega$ .

Hence, in order to construct, at least formally, fundamental solutions, the coefficients must satisfy the differential equation (3.6b). These turn out to be identifiable recursively without further assumption.

A simple case in which an explicit formula for the coefficients can be obtained when  $P$  has no first order derivatives<sup>2</sup>.

Let  $\Phi : \Omega \times [0, 1] \rightarrow \Omega$  be such that  $\Phi(y, s) = \exp_x(s \cdot \exp_x^{-1}(y))$ , which is well defined and smooth since  $\Omega$  is a geodesically starshaped set. In other words,  $\Phi$  is a parametrization of the geodesic connecting  $x$  to another point  $y \in \Omega$ , as one can see in FIGURE 3.1.

<sup>2</sup>see [5, Prop 1] and [3, Prop 2.2.4] for the general case

 FIGURE 3.1: The action of the map  $\Phi$ .

**3.2.6 Theorem.** *Let  $\Omega \subset M$  be a geodesically starshaped open subset with respect to  $x \in M$ . Let  $P$  be a generalized d'Alembert operator of the form  $P = \square + V$ , where  $V \in C^\infty(M)$ . Then there exist unique Hadamard coefficients  $V_x^k$  for  $P$  at  $x$  given by*

$$V_x^0(y) = \mu_x^{-\frac{1}{2}}(y) \quad (3.7)$$

and for  $k \geq 1$

$$V_x^k(y) = -k\mu_x^{-\frac{1}{2}}(y) \int_0^1 \mu_x^{\frac{1}{2}}(\Phi(y, s)) s^{k-1} \left( (PV_x^{k-1})\Phi(y, s) \right) ds. \quad (3.8)$$

If the point  $x$  vary and if  $\Omega$  is convex, the Riesz distributions are defined for all  $x \in \Omega$ . Write  $V^k(x, y) := V_x^k(y)$  for the Hadamard coefficients at  $x$ , equations (3.7) and (3.8) imply that  $V^k \in C^\infty(\Omega \times \Omega)$ .

**3.2.7 Definition.** *Let  $\Omega \subset M$  be convex and  $P$  a generalized d'Alembert operator as in equation (3.1). We call*

$$\mathcal{R}_\pm(x) = \sum_{k=0}^{\infty} V^k(x, \cdot) R_\pm^\Omega(2k+2, x), \quad (3.9)$$

the **retarded** or **advanced** formal fundamental solutions for  $P$  at  $x \in \Omega$ .

**3.2.8 Remark.** The coefficients  $V^k \in C^\infty(\Omega \times \Omega)$  can be calculated by the analogous of equations (3.7) and (3.8):

$$V^0(x, y) = \mu_x^{-\frac{1}{2}}(y),$$

$$V^k(x, y) = -k\mu_x^{-\frac{1}{2}}(y) \int_0^1 \mu_x^{\frac{1}{2}}(\Phi(y, s)) s^{k-1} \left( (P_{(2)}V^{k-1})\Phi(y, s) \right) ds,$$

where the subscript "(2)" in  $P_{(2)}V^{k-1}$  stands for  $P$  acting on the second variable, i.e. on  $s \mapsto V^{k-1}(\cdot, s)$ .

### 3.2.2 Approximate fundamental solutions

The series defining  $\mathcal{R}_\pm(x)$  may diverge, hence it does not provide any local fundamental solution. The idea is to make the series convergent by keeping the first terms of the formal series and multiplying the higher ones by suitable cut-off functions<sup>3</sup>.

Let  $\Omega'$  be a convex subset. Fix an integer  $N \geq \frac{n}{2}$ . Then, for all  $k \geq N$ , the distribution  $R_\pm^{\Omega'}(2k+2, x)$  is continuous on  $\Omega'$ . We split the formal fundamental solutions

$$\mathcal{R}_\pm(x) = \sum_{k=0}^{N-1} V^k(x, \cdot) R_\pm^{\Omega'}(2k+2, x) + \sum_{k=N}^{\infty} V^k(x, \cdot) R_\pm^{\Omega'}(2k+2, x).$$

**3.2.9 Proposition.** *Let  $\Omega \subset \Omega'$  be a relatively compact open subset. Let  $\sigma : \mathbb{R} \rightarrow [0, 1]$  be a smooth cut-off function with  $\text{supp } \sigma \subset [-1, 1]$  and  $\sigma = 1$  on  $[-\frac{1}{2}, \frac{1}{2}]$ . Then there exists a sequence  $\{\varepsilon_k\}_{k \geq N}$  in  $(0, 1]$ , such that, for each  $j \geq 0$ , the series*

$$\begin{aligned} (x, y) &\mapsto \sum_{k=N+j}^{\infty} \sigma\left(\frac{\Gamma_x(y)}{\varepsilon_k}\right) V^k(x, y) R_\pm^{\Omega'}(2+2k, x)(y) = \\ &= \begin{cases} \sum_{k=N+j}^{\infty} C(2+2k, n) \sigma\left(\frac{\Gamma_x(y)}{\varepsilon_k}\right) V^k(x, y) \Gamma_x(y)^{k+1-\frac{n}{2}} & \text{if } y \in J_\pm^{\Omega'}(x) \\ 0 & \text{otherwise} \end{cases} \end{aligned} \tag{3.10}$$

converges in  $C^j(\overline{\Omega} \times \overline{\Omega})$ . In particular the series

$$(x, y) \mapsto \sum_{k=N}^{\infty} \sigma\left(\frac{\Gamma_x(y)}{\varepsilon_k}\right) V^k(x, y) R_\pm^{\Omega'}(2+2k, x)(y)$$

defines a continuous function.

We use the main tools that we need to approximate the fundamental solutions<sup>4</sup>.

---

<sup>3</sup>see [3, Lem 2.2.6]

<sup>4</sup>see [3, Prop 2.2.10]

**3.2.10 Theorem.** *Let  $\Omega'$  be a convex open subset of  $M$ , let  $P$  be a generalized d'Alembert operator over  $M$ , as in equation (3.1), and  $\sigma$  a cut-off function per Proposition 3.2.9. Then, for every relatively compact open subset  $\Omega \subset \Omega'$ , there exists a positive sequence  $\{\varepsilon_k\}_{k \geq N}$ , such that for every  $x \in \overline{\Omega}$*

$$\tilde{\mathcal{R}}_{\pm}(x) = \sum_{k=0}^{N-1} V^k(x, \cdot) R_{\pm}^{\Omega'}(2k+2, x) + \sum_{k=N}^{\infty} \sigma\left(\frac{\Gamma_x(y)}{\varepsilon_k}\right) V^k(x, \cdot) R_{\pm}^{\Omega'}(2k+2, x) \quad (3.11)$$

defines a distribution on  $\Omega$  satisfying

- (1)  $\text{supp } \tilde{\mathcal{R}}_{\pm}(x) \subset J_{\pm}^{\Omega}(x)$ ,
- (2)  $P_{(2)} \tilde{\mathcal{R}}_{\pm}(x) = \delta_x + K_{\pm}(x, \cdot)$  where  $K_{\pm} \in C^{\infty}(\overline{\Omega} \times \overline{\Omega})$ ,
- (3) for every  $\varphi \in \mathcal{D}(\Omega)$ ,  $x \mapsto \left( \tilde{\mathcal{R}}_{\pm}(x), \varphi \right)$  is smooth on  $\Omega$ .

With a suitable sequence  $\{\varepsilon_k\}$  the distributions defined in equation (3.11), called approximate **retarded** or **advanced** fundamental solutions, approximate the true fundamental solutions, namely the difference  $P_{(2)} \tilde{\mathcal{R}}_{\pm}(x) - \delta_x$  is a smooth function.

### 3.2.3 True fundamental solutions

We can turn the approximate fundamental solution into a true one getting rid of the error terms<sup>5</sup>.

To start with, notice that, if a sequence  $\{\varepsilon_k\}$  gives an approximate fundamental solution for  $\Omega$ , the same sequence still provides an approximate fundamental solution for any  $\Omega_1 \subset \Omega$ .

We can read  $K_{\pm} \in C^{\infty}(\overline{\Omega} \times \overline{\Omega})$  as an integral kernel defining the smooth integral operator for any  $x \in \Omega$  and for any  $u \in C^0(\Omega)$

$$(\mathcal{K}_{\pm} u)(x) := \int_{\Omega} K_{\pm}(x, y) u(y) d\mu(y). \quad (3.12)$$

Since the map  $\varphi \mapsto (\delta_x, \varphi) : \mathcal{D}(\Omega) \rightarrow \mathcal{D}(\Omega)$  is the identity operator  $\mathbb{1}|_{\mathcal{D}(\Omega)}$ , one can rewrite equation (2) in Theorem 3.2.10 as

$$\left( P_{(2)} \tilde{\mathcal{R}}_{\pm}(x), \varphi \right) = (\mathbb{1} + \mathcal{K}_{\pm}) \varphi,$$

<sup>5</sup>we will follow [5, Sec 3.3.3] and [3, Sec 2.2.3]

for all  $\varphi \in \mathcal{D}(\Omega)$ .

We look for an inverse of  $(\mathbb{1} + \mathcal{K}_\pm)$ . Its importance can be appreciated by observing that for all  $\varphi \in \mathcal{D}(\Omega)$

$$(G_\pm^\Omega, \varphi) := (\mathbb{1} + \mathcal{K}_\pm)^{-1} \left( y \mapsto \left( \tilde{\mathcal{R}}_\pm(y), \varphi \right) \right). \quad (3.13)$$

Hence

$$\begin{aligned} (PG_\pm^\Omega(x), \varphi) &= (G_\pm^\Omega(x), P^*\varphi) \\ &= \left[ (\mathbb{1} + \mathcal{K}_\pm)^{-1} \left( y \mapsto \left( \tilde{\mathcal{R}}_\pm(y), P^*\varphi \right) \right) \right] (x) \\ &= \left[ (\mathbb{1} + \mathcal{K}_\pm)^{-1} \left( \underbrace{y \mapsto \left( P_{(2)} \tilde{\mathcal{R}}_\pm(y), \varphi \right)}_{(\mathbb{1} + \mathcal{K}_\pm) \varphi} \right) \right] (x) \\ &= \varphi(x), \end{aligned}$$

that is  $PG_\pm^\Omega(x) = \delta_x$ . If we can identify an inverse for  $\mathbb{1} + \mathcal{K}_\pm$  and if we can prove that  $G_\pm^\Omega$  is a well-defined distribution, we obtain a local **exact** fundamental solution.

The idea is to use the fact that, given a bounded operator  $A$  on a Banach space, an operator of the form  $(\mathbb{1} + A)$  is invertible if  $\|A\| < 1$ . In our case this condition can be satisfied on domains with *small* volume. To be more precise we have the following proposition<sup>6</sup>:

**3.2.11 Proposition.** *Let  $\Omega \subset \Omega'$  be a relatively compact open and causal set (see Definition 1.2.18) and assume*

$$|\overline{\Omega}| \cdot \sup_{(x,y) \in \overline{\Omega} \times \overline{\Omega}} K_\pm(x, y) < 1, \quad (3.14)$$

where  $|\overline{\Omega}| = \int_{\overline{\Omega}} d\mu$ . Then  $(\mathbb{1} + \mathcal{K}_\pm) : C^k(\overline{\Omega}) \rightarrow C^k(\overline{\Omega})$  is an isomorphism for all  $k \in \mathbb{N}$ .

The main results are:

**3.2.12 Theorem.** *Let  $P$  be a generalized d'Alembert operator on  $M$  as in equation (3.1). Then every point of  $M$  possesses a relatively compact causal open neighborhood  $\Omega$  such that*

---

<sup>6</sup>see [2, Lem 2.4.8]

- (1)  $G_{\pm}^{\Omega}(x)$ , defined in equation (3.13), are fundamental solutions for  $P$  at  $x$  over  $\Omega$ ,
- (2)  $\text{supp } G_{\pm}^{\Omega}(x) \subset J_{\pm}^{\Omega}(x)$ , i.e.  $G_{\pm}^{\Omega}(x)$  are a **retarded** and an **advanced** fundamental solution,
- (3)  $\varphi \mapsto (G_{\pm}^{\Omega}(x), \varphi)$  is smooth for all  $\varphi \in \mathcal{D}(\Omega)$ .

### 3.2.4 Asymptotic behaviour

The formal fundamental solution is asymptotic in the sense that the true fundamental solution coincides with the truncated one

$$\mathcal{R}_{\pm}^{N+j}(x) = \sum_{k=0}^{N-1+j} V^k(x, \cdot) R_{\pm}^{\Omega'}(2+2k, x),$$

up to an error term which is regular on the light cone. More precisely, for all  $j \in \mathbb{N}$  the map

$$(x, y) \mapsto (G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+j}(x))(y) \quad (3.15)$$

is in  $C^k(\Omega \times \Omega)$ . Moreover it holds:

**3.2.13 Proposition.** *For every  $j \in \mathbb{N}$  there exists a constant  $C_j$  such that*

$$\sup_{(x,y) \in \overline{\Omega} \times \overline{\Omega}} (G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+j}(x))(y) \leq C_j |\Gamma_x(y)|^j,$$

for all  $(x, y) \in \Omega \times \Omega$ .

To prove this proposition we need a lemma<sup>7</sup>.

**3.2.14 Lemma.** *Let  $f \in C^{3j+1}(\mathbb{M}^n)$  such that  $f = 0$  if  $\|x\| < 0$ . Then there exists a continuous function  $h : \mathbb{M}^n \rightarrow \mathbb{R}$  such that*

$$f(x) = h(x) \gamma(x)^j,$$

where  $\gamma(x) = -\langle x, x \rangle$ .

---

<sup>7</sup>see [3, Lem 2.2.20]

**Proof of Proposition 3.2.13.** Using the properties expressed in Theorem 3.2.2, we find constants  $C'_k$  such that

$$\begin{aligned}
 (G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+j}(x))(y) &= \\
 &= (G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+3j+1}(x))(y) + \sum_{k=N+j}^{N+3j} V^k(x, y) R_{\pm}^{\Omega'}(2+2k, x)(y) \\
 &= (G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+3j+1}(x))(y) + \\
 &+ \sum_{k=N+j}^{N+3j} V^k(x, y) C'_k \Gamma_x(y)^j R_{\pm}^{\Omega'}(2+2(k-j), x)(y).
 \end{aligned}$$

The function  $h_k(x, y) := C'_k V^k(x, y) R_{\pm}^{\Omega'}(2+2(k-j), x)(y)$  is continuous since  $2+2(k-j) \geq 2+2N \geq 2+n > n$ . In view of equation (3.15), the function  $(x, y) \mapsto (G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+3j+1}(x))(y)$  is  $C^{3j+1}$  and  $\text{supp}(G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+3j+1}(x)) \subset J_{\pm}^{\Omega}(x)$ . We apply Lemma 3.2.14 in normal coordinates (note that  $\Gamma_x(y) = \gamma(\exp_x^{-1}(y))$ ) and find a continuous function  $h$  such that

$$(G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+3j+1}(x))(y) = h(x, y) \Gamma_x(y)^k.$$

Hence,

$$(G_{\pm}^{\Omega}(x) - \mathcal{R}_{\pm}^{N+j}(x))(y) = \left( h(x, y) + \sum_{k=N+j}^{N+3j} h_k(x, y) \right) \Gamma_x(y)^j.$$

If we now set  $C_j := \sup_{(x,y) \in \bar{\Omega} \times \bar{\Omega}} \left( h(x, y) + \sum_{k=N+j}^{N+3j} h_k(x, y) \right)$  the proposition is proven.  $\blacksquare$

### 3.2.5 Uniqueness and regularity

We want to solve the inhomogeneous equation  $Pu = \psi$  for a given  $\psi$  with small support, *small* in the sense of Proposition 3.2.11. The support  $\Omega$  is relatively compact and equation (3.14) holds.

**3.2.15 Proposition.** *Under the assumption of Proposition 3.2.11, for every  $\psi \in \mathcal{D}(\Omega)$  there exists a function  $u_{\pm} \in C^{\infty}(\Omega)$  such that*

$$\begin{aligned}
 Pu_{\pm} &= \psi \\
 \text{supp } u_{\pm} &\subset J_{\pm}^{\Omega}(\text{supp } \psi).
 \end{aligned}$$

**Proof.** Let

$$(u_{\pm}, \varphi) := \int_{\Omega} (G_{\pm}^{\Omega}(x), \varphi) \psi(x) d\mu. \quad (3.16)$$

We will not prove that equation (3.16) defines a smooth function, rather only  $Pu_{\pm} = \psi$ . Let  $\varphi \in \mathcal{D}(\Omega)$ . It holds

$$\begin{aligned} (Pu_{\pm}, \varphi) &= (u_{\pm}, P^* \varphi) \\ &= \int_{\Omega} (G_{\pm}^{\Omega}(x), P^* \varphi) \psi(x) d\mu \\ &= \int_{\Omega} \underbrace{(P_{(2)} G_{\pm}^{\Omega}(x), \varphi)}_{=\delta_x} \psi(x) d\mu \\ &= \int_{\Omega} \varphi(x) \psi(x) d\mu = (\psi, \varphi). \end{aligned}$$

To prove the support condition, let  $\varphi \in \mathcal{D}(\Omega)$  such that  $(u_{\pm}, \varphi) \neq 0$ , then there exists  $x \in \Omega$  such that  $(G_{\pm}^{\Omega}(x), \varphi) \psi(x) \neq 0$ , which implies  $\text{supp } \varphi \cap \text{supp } G_{\pm}^{\Omega}(x) \neq \emptyset$  and  $x \in \text{supp } \psi$ . Hence  $\text{supp } \varphi \cap J_{\pm}^{\Omega}(x) \neq \emptyset$ , i.e.  $x \in J_{\mp}^{\Omega}(\text{supp } \varphi)$ , so that  $J_{\mp}^{\Omega}(\text{supp } \varphi) \cap \text{supp } \psi$ , which is equivalent to the thesis. ■

As we mentioned in Proposition 1.2.19, the topological and geometrical properties of the Lorentzian manifold may be problematic when we are looking for solutions of a differential equation. For example, even if the manifold is not compact, the existence of closed timelike loops can make the problem ill-posed. To avoid these situations and to implement the causality conditions we restrict the discussion to the **globally hyperbolic** setting (see Definition 1.2.21), although some results may be extended to other cases.

In such case the main results are

**3.2.16 Theorem.** *Let  $P$  be a generalized d'Alembert operator on a globally hyperbolic spacetime  $M$  as in equation (3.1). Then every solution of the equation  $PF = 0$  in  $\mathcal{D}'(M)$  with past- or future-compact support (see Definition 1.2.18) vanishes.*

**Sketch of proof.** Take the case  $F \in \mathcal{D}'(\Omega)$  with past-compact support. The thesis is  $(F, \varphi) = 0$  for any  $\varphi \in \mathcal{D}(M)$ . The idea is to solve the inhomogeneous equation

$$\begin{aligned} P^* u &= \varphi \\ \text{supp } u &\subset J_{-}^{\Omega}(\text{supp } \varphi) \end{aligned}$$

(using Proposition 3.2.15) for any  $\varphi$  such that  $\text{supp } \varphi$  is small in the sense expressed in Proposition 3.2.11. If one proves that  $\text{supp } F \cap J_-^\Omega(\text{supp } \varphi)$  is compact, it holds

$$(F, \varphi) = (F, P^*u) = (PF, u) = 0.$$

The proof of such properties involves the global hyperbolicity of the manifold. For the complete proof see [3, Sec 2.3] ■

Now uniqueness is straightforward:

**3.2.17 Corollary.** *Let  $P$  be a generalized d'Alembert operator on a globally hyperbolic spacetime  $M$  as in equation (3.1) and let  $x \in M$ . Then there exist at most one retarded and at most one advanced fundamental solution for  $P$  at  $x$ .*

**Proof.** Let  $G_1$  and  $G_2$  be two retarded fundamental solutions at  $x$ . Then  $G = G_1 - G_2$  is a solution for  $PG = 0$ . Since  $G_1$  and  $G_2$  are retarded solutions we know that  $\text{supp } G \subset \text{supp } G_1 \cup \text{supp } G_2 \subset J_+^M(x)$ . On a globally hyperbolic manifold  $J_+^M(x)$  is past compact. Then for Theorem 3.2.16  $G = 0$  and hence  $G_1 = G_2$ . ■

### 3.3 Local and global Cauchy problem

We now explore the solvability of the Cauchy problem, in analogy with Section 2.6, in order to obtain results needed to prove the existence and uniqueness of the fundamental solutions.

#### 3.3.1 Local solvability

Next we prove existence and uniqueness of solutions to the Cauchy problem on small domains. To start with, it is useful to show a formula that helps controlling a solution of the problem in terms of its initial data<sup>8</sup>. This theorem and its corollary are the analogous of Theorem 2.6.4 and Corollary 2.6.5, which can be regarded as particular cases.

**3.3.1 Theorem.** *Let  $P$  be a generalized d'Alembert operator on  $M$ , as in equation (3.1), and let  $S$  be a smooth spacelike hypersurface of  $M$  with a timelike oriented unit normal vector field  $n : S \rightarrow TM$ .*

*Let  $\Omega \subset M$  be a small subset in the sense of Proposition 3.2.11 such that  $S \cap \Omega$*

---

<sup>8</sup>see [3, Lem 3.2.2]

is a Cauchy hypersurface of  $\Omega$ . If  $u_{\pm} \in C^{\infty}(\Omega)$  such that  $\text{supp } u_{\pm} \subset J_{\pm}^{\Omega}(K)$  (where  $K := \text{supp } u_0 \cup \text{supp } u_1 \cup \text{supp } \psi$ ) solve the Cauchy problem

$$\begin{cases} Pu_{\pm} = \psi \\ u_{\pm}|_{S \cap \Omega} = u_0 \\ \partial_n u_{\pm}|_{S \cap \Omega} = u_1, \end{cases} \quad (3.17)$$

with  $(\psi, u_0, u_1) \in \mathcal{D}(\Omega) \oplus \mathcal{D}(S \cap \Omega) \oplus \mathcal{D}(S \cap \Omega)$ , then it holds

$$\begin{aligned} \int_{\Omega} u_{\pm}(x) \varphi(x) \, d\mu &= \int_{\Omega} (G_{\pm}^{\Omega}(x), \varphi) \psi(x) \, d\mu + \\ &+ \int_{S \cap \Omega} (\partial_n(G_{\pm}^{\Omega}(x), \varphi) u_0 - (G_{\pm}^{\Omega}(x), \varphi) u_1) \, d\mu_S, \end{aligned} \quad (3.18)$$

for all  $\varphi \in \mathcal{D}(\Omega)$ , where  $d\mu_S$  is the  $n-1$  dimensional pull-back measure on  $S$ .<sup>9</sup>

**3.3.2 Corollary.** In the conditions of last lemma, if  $u \in C^{\infty}(\Omega)$  solves  $Pu = 0$  then

$$\text{supp } u \subset J_+^{\Omega}(K) \cup J_-^{\Omega}(K),$$

where  $K := \text{supp } u_0 \cup \text{supp } u_1$ , and

$$\int_{\Omega} u(x) \varphi(x) \, d\mu = \int_{S \cap \Omega} (\partial_n(G^{\Omega}(x), \varphi) u_0 - (G^{\Omega}(x), \varphi) u_1) \, d\mu_S, \quad (3.19)$$

for all  $\varphi \in \mathcal{D}(\Omega)$ , where  $G^{\Omega}(x) = G_+^{\Omega}(x) - G_-^{\Omega}(x)$  and where  $d\mu_S$  is the  $n-1$  dimensional pull-back measure on  $S$ .

**Proof.** We apply Theorem 3.3.1 with  $\psi = 0$ , noting that one can write  $u$  in the form  $u = u_+ - u_-$  such that  $\text{supp } u_{\pm} \subset J_{\pm}^{\Omega}(K)$ . Using equations (3.18) for both  $u_+$  and  $u_-$  and subtracting the outcomes, we obtain the thesis. Since  $\text{supp } G_{\pm}^{\Omega}(x) \subset J_{\pm}^{\Omega}(x)$ , the right hand side of equation (3.18) vanishes outside  $J_+(K) \cup J_-(K)$ , hence  $\text{supp } u \subset J_+(K) \cup J_-(K)$ . ■

**3.3.3 Theorem.** Under the hypotheses of Lemma 3.3.1, for each small open subset  $\Omega \subset M$ , such that the hypotheses of Proposition 3.2.11 are satisfied,

<sup>9</sup>Pull-back measure are defined in [6, Ch. 1]

such that  $S \cap \Omega$  is a Cauchy hypersurface of  $\Omega$ , it holds that for all triples  $(\psi, u_0, u_1) \in \mathcal{D}(\Omega) \oplus \mathcal{D}(S \cap \Omega) \oplus \mathcal{D}(S \cap \Omega)$  there exists a unique  $u \in C^\infty(\Omega)$  with

$$\begin{cases} Pu = \psi \\ u|_{S \cap \Omega} = u_0 \\ \partial_n u|_{S \cap \Omega} = u_1. \end{cases} \quad (3.20)$$

Moreover  $\text{supp } u \subset J_+^\Omega(K) \cup J_-^\Omega(K)$ , where  $K := \text{supp } u_0 \cup \text{supp } u_1 \cup \text{supp } \psi$ .

**Sketch of proof.** Since causal domains are globally hyperbolic we may apply Theorem 1.2.23 to find an isometry  $\Omega = \mathbb{R} \times (S \cap \Omega)$ , setting the metric in the form  $g = -\beta dt^2 + b_t$ . Now we look for a formal solution

$$u(t, x) = \sum_{j=0}^{\infty} t^j \tilde{u}_j(x), \quad (3.21)$$

where  $(t, x) \in \mathbb{R} \times (S \cap \Omega)$ . On  $S \cap \Omega$  we set  $\tilde{u}_0 = u_0$  and  $\tilde{u}_1 = -(\beta)^{\frac{1}{2}} u_1$ . The generalized d'Alembert operator can be written in the form  $P = \frac{1}{\beta} \frac{\partial^2}{\partial t^2} + Y$ , where  $Y$  contains at most derivatives of order 1 in  $t$ .

From the equation

$$\psi = Pu = \left( \frac{1}{\beta} \frac{\partial^2}{\partial t^2} + Y \right) u = \frac{1}{\beta} \sum_{j=2}^{\infty} j(j-1) t^{j-2} \tilde{u}_j + Yu, \quad (3.22)$$

for  $t = 0$  we have

$$2\beta(0, x) \tilde{u}_2(x) = -Y(\tilde{u}_0 + t\tilde{u}_1)(0, x) + \psi(0, x).$$

This relation determines uniquely  $\tilde{u}_2$  from  $\tilde{u}_0, \tilde{u}_1$  and  $\psi|_S$ . One can hence find recursive relations for  $\tilde{u}_j$  differentiating equation (3.22) with respect to  $t$  and repeating the procedure.

In general the series in equation (3.21) is non-convergent, but one can find a suitable positive sequence  $\{\varepsilon_j\}$  such that the series

$$\hat{u} := \sum_{j=0}^{\infty} \sigma\left(\frac{t}{\varepsilon_j}\right) t^j \tilde{u}_j,$$

FIGURE 3.2: The support properties of the solution to the Cauchy problem. Here  $K := \text{supp } u_0 \cup \text{supp } u_1 \cup \text{supp } \psi$ .

defines a smooth function on  $\Omega$  and such that  $P\hat{u} - \psi$  vanishes at least on  $S \cap \Omega$ . Here  $\sigma$  is a cut-off function as in Proposition 3.2.9. Proposition 3.2.15 provides smooth solutions  $\tilde{u}_\pm$  of the inhomogeneous problems

$$\begin{aligned} P\tilde{u}_\pm &= h_\pm \\ \text{supp } \tilde{u}_\pm &\subset J_\pm^\Omega(\text{supp } h_\pm), \end{aligned}$$

where  $h_\pm|_{J_\pm^\Omega(S \cap \Omega)} := P\hat{u} - \psi$  vanishes everywhere else on  $\Omega$ . One needs to show that  $u_\pm := \hat{u} - \tilde{u}_\pm$  solves the equation  $Pu_\pm = \psi$  on  $J_\pm^\Omega(S \cap \Omega)$  and that it vanishes on  $J_\mp^\Omega(S \cap \Omega)$ . Then the function

$$u := \begin{cases} u_+ & \text{on } J_+^\Omega(S \cap \Omega) \\ u_- & \text{on } J_-^\Omega(S \cap \Omega) \end{cases}$$

is smooth and it solves the Cauchy problem.

Uniqueness follows from Corollary 3.3.2. In fact, if  $u_1$  and  $u_2$  solve the Cauchy problem, for linearity  $u_1 - u_2$  solves the problem with vanishing initial data  $(\psi, u_0, u_1) \equiv (0, 0, 0)$ . Hence  $u := u_1 - u_2 = 0$  because of equation (3.19). The assertion of the support follows from the corresponding one from the homogeneous problem and from Corollary 3.3.2. For a complete proof, see [3, Prop 2.4.1]. ■

### 3.3.2 Global solvability

The main result of this section generalizes what we obtained in Theorem 3.3.3 to the globally hyperbolic case.

**3.3.4 Theorem.** *Let  $P$  be a generalized d'Alembert operator on a globally hyperbolic spacetime  $M$ , as in equation (3.1), and let  $S$  be a smooth Cauchy hypersurface of  $M$  with a timelike oriented unit normal vector field  $n : S \rightarrow TM$ . Then it holds that for all triples  $(\psi, u_0, u_1) \in \mathcal{D}(M) \oplus \mathcal{D}(S) \oplus \mathcal{D}(S)$  there exists a unique  $u \in C^\infty(M)$  such that*

$$\begin{cases} Pu = \psi \\ u|_S = u_0 \\ \partial_n u|_S = u_1. \end{cases} \quad (3.23)$$

Furthermore  $\text{supp } u \subset J_+^M(K) \cup J_-^M(K)$ , where  $K := \text{supp } u_0 \cup \text{supp } u_1 \cup \text{supp } \psi$  and the map

$$\begin{aligned} \mathcal{D}(M) \oplus \mathcal{D}(S) \oplus \mathcal{D}(S) &\rightarrow C^\infty(M) \\ (\psi, u_0, u_1) &\mapsto u. \end{aligned}$$

is **linear continuous**.

**Sketch of proof.** The existence of  $u$  is proved in two steps. One constructs a solution  $u$  in the strip  $(-\varepsilon, \varepsilon) \times S$  for some  $\varepsilon > 0$  by gluing together local solutions obtained in Theorem 3.3.3, noting that there is only a finite number of them since the supports are compact. Then one extends  $u$  in the whole future and past of the strip. For uniqueness, an argument similar to that of Theorem 3.3.3, which made use of Corollary 3.3.2, can be used.

The continuous dependence on the initial data can be proven with methods of functional analysis. The complete proof can be found at [3, Th. 3.2.9] ■

**3.3.5 Remark.** The former result can be extended further. In fact the same thesis holds even if the triple of initial data  $(\psi, u_0, u_1)$  is in  $C^\infty(M) \oplus C^\infty(S) \oplus C^\infty(S)$ <sup>10</sup>.

## 3.4 Global fundamental solutions

Since uniqueness of the retarded and advanced fundamental solutions has already been proven in Corollary 3.2.17, it remains to show the global existence. We summarize the results in the following theorem<sup>11</sup>.

---

<sup>10</sup>see [5, Cor 5]

<sup>11</sup>see [5, Th. 4]

**3.4.1 Theorem.** *Let  $P$  be a generalized d'Alembert operator on a globally hyperbolic spacetime  $M$ , as in equation (3.1). Then for each  $x \in M$  there exists a unique fundamental solution  $G_+(x)$  with past-compact support and a unique one  $G_-(x)$  with future-compact support.*

*Furthermore, they satisfy*

- $\text{supp } G_{\pm} \subset J_{\pm}^M(x)$ ,
- *the maps  $x \mapsto (G_{\pm}(x), \varphi)$  identify smooth functions on  $M$  satisfying  $P^*(G_{\pm}(\cdot), \varphi) = \varphi$ , for every  $\varphi \in \mathcal{D}(M)$ .*

**3.4.2 Remark.** From the last theorem one can prove that on a globally hyperbolic spacetime, the wave-like equation  $Pu = \psi$ , with  $\psi \in \mathcal{D}(M)$  possesses a unique solution  $u_{\pm}$  with  $\text{supp } u_+$  (respectively  $\text{supp } u_-$ ) being past (respectively future) compact.

## 3.5 Green's operators

We want to show the strict correspondence between fundamental solutions on manifolds and the so-called **Green's operators**. They are operators which can be seen as inverses of  $P$  when restricted to suitable spaces of functions.

**3.5.1 Definition.** *Let  $P$  be a generalized d'Alembert operator on a spacetime  $M$ . A retarded **Green's operator** for  $P$  on  $M$  is a linear map*

$$\mathbb{G}_+ : \mathcal{D}(M) \rightarrow C^\infty(M)$$

*such that satisfies*

- (1)  $P \circ \mathbb{G}_+ = \mathbb{1}_{\mathcal{D}(M)}$ ,
- (2)  $\mathbb{G}_+ \circ P|_{\mathcal{D}(M)} = \mathbb{1}_{\mathcal{D}(M)}$ ,
1.  $\text{supp } \mathbb{G}_+ \varphi \subset J_+^M(\text{supp } \varphi)$  for all  $\varphi \in \mathcal{D}(M)$ .

*An advanced **Green's operator**  $\mathbb{G}_- : \mathcal{D}(M) \rightarrow C^\infty(M)$  satisfies (1) and (2) and  $\text{supp } \mathbb{G}_- \varphi \subset J_-^M(\text{supp } \varphi)$  for all  $\varphi \in \mathcal{D}(M)$ .*

Next proposition shows that in fact Green's operators and fundamental solutions are two different versions of mainly the same concept.

**3.5.2 Proposition.** *In the frame of the above definition, retarded (resp. advanced) Green's operators for  $P$  stand in one-to-one correspondence with advanced (resp. retarded) fundamental solutions for  $P^*$ . More precisely, if  $G_{\pm}(x)$  is a family of retarded or advanced fundamental solutions for the adjoint operator  $P^*$  and if*

- $x \mapsto (G_{\pm}(x), \varphi)$  is smooth for each test-function  $\varphi$ ,
- $G_{\pm}(x)$  satisfies the differential equation  $P(G_{\pm}(\cdot), \varphi) = \varphi$

, then

$$(\mathbb{G}_{\pm}\varphi)(x) := (G_{\mp}(x), \varphi), \quad (3.24)$$

defines retarded or advanced Green's operators for  $P$  respectively.

Conversely, for every Green's operators  $\mathbb{G}_{\pm}$  for  $P$ , equation (3.24) defines fundamental solutions  $G_{\mp}(x)$  such that  $x \mapsto (G_{\pm}(x), \varphi)$  is smooth for each test-function  $\varphi$  and satisfies the differential equation  $P(G_{\pm}(\cdot), \varphi) = \varphi$ .

## Conclusions

---

In this thesis we described the local and global well-posedness of wave-like equations propagating on a curved globally hyperbolic Lorentzian manifold, using the method of fundamental solutions.

In particular we outlined the construction of two fundamental solutions  $G_+$  and  $G_-$ , the *retarded* and the *advanced* one, that propagate the source of the equation respectively in the causal future and in the causal past, in accordance with the causality principle.

In Chapter 2, we addressed the problem of solving the wave operator on Minkowski spacetime via the theory of Fourier transform. This relies on the existence of a translation group, a feature which is indeed enjoyed by Minkowski spacetime. Therefore, they are not well-suited for a generic curved background, such as Schwarzschild or cosmological spacetimes, which lack in general of such symmetries.

We showed explicit formulas for the wave operator on Minkowski spacetime with dimensions  $2 \leq n \leq 4$  with Fourier transform. Then to deduce general properties of solutions, we introduced the *Riesz distributions*, a family of distributions  $R_{\pm}(\alpha)$  with which we equivalently solved the problem, but that are more suitable for further generalizations. We addressed the Cauchy problem on flat space, realizing that it is well posed if the initial data are set on a particular class of hypersurfaces: Cauchy hypersurfaces (see Definition 1.2.22). In Chapter 3 we focus on the wave propagation problem on a suitably Lorentzian manifold. In particular, we extended the Riesz distributions locally on generic

Lorentzian manifolds and combined them in order to obtain local fundamental solutions. Gluing together local solutions, we subsequently found that if the manifold respects the condition of *global hyperbolicity*, which is equivalent to the request of the existence of a Cauchy hypersurface, we can construct a global and smooth solution to the Cauchy problem, maintaining the local support properties.

Globally hyperbolic Lorentzian manifolds turned out to form a good class for the solution theory of wave-like operators. On them we have unique advanced and retarded fundamental solutions and the global Cauchy problem is well-posed.

The possible extensions and follow-ups of this work are many. Firstly, the results can be extended to differential operators that act on sections of vector bundles, in other words, to vector valued fields, such as the vector potential in electromagnetism. This opens the door of quantum fields theory on curved backgrounds, whose aim is to provide a partial unification of General Relativity with Quantum Physics where the gravitational field is left classical while the other fields are quantized<sup>12</sup>. In particular one can deal with other operators such as Dirac operator  $D$ , whose square is a wave-like operator, as well as with free electrodynamics, both starting from the vector potential or from the Faraday tensor.. Other extensions may go in the direction of addressing the global problem in non-globally hyperbolic manifolds, since most basic models in General Relativity turn out to be globally hyperbolic, but there are exceptions such as anti-deSitter spacetime.

---

<sup>12</sup>see [11].

Firstly, we recall the main concepts of the theory of distributions on manifolds following the approach of [9].

For a manifold  $M$  we define  $\mathcal{D}(M) := C_0^\infty(M)$  as the space of test-functions on  $M$ . We say a sequence  $\{\varphi_k\}_{k \in \mathbb{N}}$  of  $\mathcal{D}(M)$  (with  $j \in \mathbb{N} \cup +\infty$ ) converges to  $\varphi \in \mathcal{D}(M)$  if there exists a compact subset  $K \subset M$  such that  $\text{supp } \varphi_k \subset K$  and, fixed any connection on  $M$ , all the derivatives of  $\varphi_k$  up to the  $j$ -th order converge uniformly in  $K$ .

A linear map  $u : \mathcal{D}(M) \rightarrow \mathbb{C}$  is continuous if for all sequences  $\{\varphi_k\}_{k \in \mathbb{N}}$  of  $\mathcal{D}(M)$  that converge to  $\varphi \in \mathcal{D}(M)$ ,  $(u, \varphi_k) \rightarrow (u, \varphi)$ , where with  $(u, \varphi)$  we denote the map  $u$  tested against  $\varphi$ .

**A.0.1 Definition.** *The space of distributions over  $M$  is defined as*

$$\mathcal{D}'(M) = \{u : \mathcal{D}(M) \rightarrow \mathbb{C} \text{ linear and continuous} \}.$$

*The support of a distribution is the set  $M \setminus X$ , where  $X$  is the set of points  $x \in M$  such that there exists a neighborhood  $U$  of  $x$  such that  $u|_{\mathcal{D}(U)} \neq 0$ . We say  $u \in \mathcal{E}'(M)$  if  $\text{supp } u$  is a compact subset of  $M$ .*

We call  $u \in \mathcal{D}'(M)$  the **weak limit** of a sequence of distributions  $\{u_i\}_{i \in \mathbb{N}}$  if for all  $\varphi \in \mathcal{D}(M)$  holds  $\lim_{i \rightarrow \infty} (u_i, \varphi) = (u, \varphi)$ .

**A.0.2 Remark.** For any fixed  $f \in C^\infty(M)$  the map  $\varphi \mapsto \int_M f(x) \varphi(x) d\mu$  defines a distribution on  $M$ . We denote this distribution again by  $f$ , hence we

identify  $C^\infty(M)$  as a subset of  $\mathcal{D}'(M)$ .

**A.0.3 Definition.** We define the translation operator  $T_{x_0} : \mathcal{D}'(\mathbb{R}^n) \rightarrow \mathcal{D}'(\mathbb{R}^n)$  such that if  $u \in \mathcal{D}'(\mathbb{R}^n)$ ,

$$(T_{x_0}u, \varphi(x)) = (u, \varphi(x + x_0)),$$

for all  $\varphi \in \mathcal{D}(\mathbb{R}^n)$ . We write  $u(x - x_0) := T_{x_0}u$ .

**A.0.4 Example.** Given  $x \in M$  the **Dirac delta**  $\delta_x$  is a distribution defined for  $\varphi \in \mathcal{D}'(M)$  by

$$(\delta_x, \varphi) = \varphi(x).$$

If  $M$  is isomorphic to  $\mathbb{R}^n$ , a particularly useful formula gives

$$\delta(x^2 - a^2) = \frac{1}{2|a|} [\delta(x - a) + \delta(x + a)]. \quad (\text{A.1})$$

**A.0.5 Definition.** We define the tensor product of two distributions  $u \in \mathcal{D}'(M)$  and  $v \in \mathcal{D}'(N)$  as the unique distribution  $u \otimes v \in \mathcal{D}'(M \times N)$  such that for any  $f \otimes g \in \mathcal{D}(M) \otimes \mathcal{D}(N)$

$$(u \otimes v, f(x)g(y)) = (u, f)(v, g).$$

Given a differential operator  $P : C^\infty(M) \rightarrow C^\infty(M)$  there is a unique  $P^* : C^\infty(M) \rightarrow C^\infty(M)$ , called the **formal adjoint** of  $P$  such that for any  $\varphi, \psi \in \mathcal{D}(M)$  holds

$$\int_M \psi(P\varphi) d\mu = \int_M (P^*\psi)\varphi d\mu.$$

Any linear differential operator  $P$  extends canonically to  $P : \mathcal{D}'(M) \rightarrow \mathcal{D}'(M)$  by

$$(Pu, \varphi) = (u, P^*\varphi).$$

In particular, we define the product of a distribution  $u \in \mathcal{D}'(M)$  with a function  $f \in C^\infty(M)$  as the distribution  $f \cdot u$  such that  $(f \cdot u, \varphi) = (u, f\varphi)$  for any  $\varphi \in \mathcal{D}(M)$ .

**A.0.6 Definition.** Let  $u \in \mathcal{E}'(\mathbb{R}^n)$  and  $v \in \mathcal{D}'(\mathbb{R}^n)$ . We define the **convolution** of  $u$  and  $v$  as the unique distribution  $u * v \in \mathcal{D}'(\mathbb{R}^n)$  such that

$$(u * v, \varphi) = (u \otimes v, \varphi(x + y)) = (v, (T_y u, \varphi)) = (u, (T_y v, \varphi)).$$

**A.0.7 Theorem.** Let  $u \in \mathcal{D}'(\mathbb{R}^n)$  and  $\rho \in \mathcal{D}(\mathbb{R}^n)$ . Then  $\rho * u \in C^\infty(\mathbb{R}^n)$ .

---

Now we recall the main concepts of Fourier theory on  $\mathbb{R}^n$ .

We call Schwartz space  $\mathcal{S}(\mathbb{R}^n)$  the set of rapidly decreasing functions, i.e. the functions  $f \in C^\infty(\mathbb{R}^n)$  such that

$$\lim_{|x| \rightarrow \infty} x^\alpha \partial^\beta f(x) = 0,$$

for any multi-index  $\alpha, \beta \in \mathbb{N}^n$ . A sequence  $\{f_j\}_{j \in \mathbb{N}}$  of rapidly decreasing functions converge to  $f$  in  $\mathcal{S}(\mathbb{R}^n)$  if for any multi-index  $\alpha, \beta \in \mathbb{N}^n$

$$\sup_{x \in \mathbb{R}^n} |x^\alpha \partial^\beta (f_j - f)(x)| \rightarrow 0,$$

as  $j \rightarrow \infty$ .

**A.0.8 Definition.** A linear functional  $u : \mathcal{S}(\mathbb{R}^n) \rightarrow \mathbb{C}$  is called a **tempered distribution** if for all sequences  $\{f_k\}_{k \in \mathbb{N}}$  of  $\mathcal{S}(\mathbb{R}^n)$  that converge to  $f \in \mathcal{S}(\mathbb{R}^n)$ ,  $(u, f_k) \rightarrow (u, f)$ . The set of tempered distribution is denoted with  $\mathcal{S}'(\mathbb{R}^n)$ .

Given a scalar product  $\langle \cdot, \cdot \rangle$  on  $\mathbb{R}^n$ , the Fourier transform  $\widehat{f}$  of a function  $f \in L^1(\mathbb{R}^n)$  is defined as

$$\widehat{f}(k) = \int_{\mathbb{R}^n} f(x) e^{-i\langle k, x \rangle} dx \quad (\text{A.2})$$

We naturally extend the Fourier transform to a unitary map  $L^2(\mathbb{R}^n) \rightarrow L^2(\mathbb{R}^n)$  and to a map on tempered distributions in such a way that for  $u \in \mathcal{S}'(\mathbb{R}^n)$  holds

$$(\widehat{u}, \varphi) = (u, \widehat{\varphi}),$$

for any  $\varphi \in \mathcal{S}(\mathbb{R}^n)$ . If  $u \in \mathcal{E}'(\mathbb{R}^n)$  holds

$$\widehat{u}(k) = \left( u, e^{-i\langle k, x \rangle} \right),$$

and  $\widehat{u}$  results a smooth function which extends to an entire function  $\widehat{u}(z)$ ,  $z \in \mathbb{C}$ .

The inverse Fourier transform of  $f \in L^1(\mathbb{R}^n)$  is given as  $\check{f}(x) := (2\pi)^{-n} \widehat{f}(-x)$  and it holds that  $f = \check{\check{f}}$ .

The Fourier transform of the distribution  $\delta \in \mathcal{E}'(\mathcal{U})$  is  $\widehat{\delta}(k) = 1$ . This is a straightforward computation:

$$\widehat{\delta}(k) = (\delta(x), e^{-i\langle k, x \rangle}) = e^0 = 1.$$

Other useful formulas that holds for  $\varphi \in \mathcal{S}'(\mathbb{R}^n)$  and for any multi-index  $\alpha$  are

- $\widehat{\partial^\alpha \varphi}(k) = (ik)^\alpha \widehat{\varphi}(k)$
- $\widehat{x^\alpha \varphi}(k) = (i\partial)^\alpha \widehat{\varphi}(k).$

# Acknowledgements

Ebbene sì, sono riuscito a scrivere correttamente la parola *acknowledgements*, ma questo non implica che io abbia la voglia di scriverli in inglese. Infatti non lo farò.

Solitamente, giunti alla fine del corso di laurea, si ringraziano parenti, amici, professori. Ricordarli e ringraziarli tutti sarebbe impossibile, anche perchè in questi tre anni credo di averne passate talmente tante insieme a tante persone, che la mia povera testolina ha dovuto rimuoverne la maggior parte per fare spazio alle ben meno importanti formule matematiche.

Cerchiamo di mettere ordine. Rubens Longhi approda a Pavia nel lontano 2015, dopo un'estate di delusioni da test d'ingresso falliti. Maledetto sia Edipo. A sostenermi in questo momento difficile c'è la decennale amica Michela, con la quale divido un appartamento per il primo anno di università. Durante quell'anno molti sono i nuovi amici, sebbene il tornare a casa ogni finesettimana mi permette di mantenere vive le amicizie di sempre.

L'inizio non è facile. Ricordo i primi giorni a fisica: io, Pozzo e Mondini emarginati in un angolo, che tentavamo di seguire il Gila senza troppo interagire con il restante centinaio di persone, tra le quali si potevano individuare quegli 8 disagiati del Ghislieri. Mamma mia quanto se la tiravano. Soprattutto un terroncello di nome Angelo e quell'altro torrione di Magoni che, dopo aver affrontato con me i test d'ingresso, mi aveva abbandonato come si fa coi cani in tangenziale. A proposito di Cane, il mio primo ricordo di Amodio Carleo si colloca in una lezione di Algebra lineare durante la quale Carleo Amodio (ma qual'è il nome?) sviene platealmente a seguito di bravate della notte precedente che gli hanno lasciato escoriazioni sulle ginocchia; anche se detto così suona male. (By the way, Pirola andò nel pallone e chiese ad un'aula gremita di fisici e matematici se ci fosse un dottore). Inizio quindi a chiedermi cosa mai faranno in quel collegio per giungere al punto di svenire a lezione. Trovai solo molto più tardi la risposta.

Dopo pochi giorni entro in contatto con le persone che sarebbero stati al centro

del mio primo anno qui: Ale Triple, Monte, Nicole, Bonfo, Vix, Piazza e poi Bressi. I mercoledì sera con loro erano diventati una tappa obbligata della settimana pavese. Benedetto fu l'ingresso gratis al Camillo.

L'amicizia con Ale Triacca si rivela importante: accomunati dal fatto di essere dei morti di figa, durante il primo anno facciamo strage di ragazzine al Camillo. Cioè, lui fa strage e io finisce che bevo e ballo in maniera ridicola (sì, avete presente come ballo).

Il martedì, invece, diventa il giorno del vino di dubbia qualità che Berti portava nel nostro appartamento nell'evidente tentativo di far ubriacare la Michela e poi sedurla. Ma la Michela, almeno ai tempi, non beveva. Inoltre il gruppo di Amaldini fuori sede a Pavia, tra cui Roby, Nicole, Losa e Pozzo si organizza con serate a tema *panterona* (gli interessati sanno di chi sto parlando) nelle quali io e Pozzo diamo del nostro peggio.

Gli esami del primo anno (a parte Chimica, che fa cagare) vanno abbastanza bene da indurmi a fare la follia: spinto anche dai consigli della Marveggio (con la quale solevo andare a bere una birra dopo ogni esame nell'evidente tentativo di sedurla; ma anche lei, ai tempi, non beveva), decido di rifare il test d'ingresso per il Ghislieri.

Stavolta l'esito è positivo: sia benedetto Rotondi che riciclò gli esercizi dell'esame di Meccanica per la prova Iuss. In quel momento tante cose cambiano. Il legame con i miei compagni d'anno collegiali diventa molto forte, anche grazie al kulo, e mi fa quasi dimenticare di essere un anno in ritardo. La mia vita viene completamente assorbita dal collegio, tanto che i periodi che passo a casa iniziano a ridursi davvero al minimo sindacale. Delle amicizie bergamasche si salvano solo quella immortale con mio cugino Daniel e quelle con i miei compagni del liceo, specialmente Pizzo, Giordano, Giulia, Giovanni, Menni e, quando c'è da far serata ignorante, anche Lanceni. Le cene con Berti, non essendo più in appartamento, deficitano della presenza della Michela e quindi lui è costretto a tentare di sedurre me.

La mia vita diventa un tuttuno con quella del mio vicino di stanza Djerme, giovane padawan nell'arte dell'analisi. Il fortissimo legame che si è creato tra di noi mi ha permesso di superare molte delle difficoltà del secondo anno: specialmente il maledetto Elettro 2. Il caffè di Allegria diventa il covo di fisici e matematici come Martina, Zio Sam, Vitto, Mago, Cane, Nino e anche di altri futuri disoccupati come Maria Ganja, Francesca (quella di Nino), Cazzato e Virginia.

Lì scopro che quel terroncello cazzone di Angelo possiede, inspiegabilmente, un cervello e che esso lavora e impara le cose esattamente come lo fa il mio: ovvero completamente a caso, senza una particolare tecnica mnemonica e senza uno studio sistematico. Questo disordine mentale comune ci porta ad

affrontare molti esami insieme e a condividere mille momenti anche sui social, fino al punto da diventare decisamente rompicoglioni (questa cosa mi mancherà parecchio).

I corsi del secondo anno sono decisamente stimolanti, anche e soprattutto perchè non li frequento, dato che chi è in collegio sa bene che nei primi mesi svegliarsi in tempo al mattino non è sempre facile. Per fortuna (o per sfortuna) le esercitazioni di Meccanica Razionale, tenute da tale Claudio Dappiaggi, sono al pomeriggio. Di quelle lezioni mi è rimasta la frase *Non crediate che i vostri professori bevano meno di voi*, la quale mi ha fatto capire di essermi ben instradato nel ruolo del fisico teorico. Al secondo anno incontriamo il Dappia in ben due esami e già lì iniziamo a pensare che ci perseguiti.

Il viaggio al *Cern*, per quanto stimolante, non mi fa recedere dai miei insani propositi teorici, anche se la coppia di prof sperimentali Negri+Rebuzzi ci fa vivere emozioni incredibili, come quando la Rebu ha detto a Nino di buttarsi dal trampolino nel lago di Ginevra, e lui ha eseguito.

Pian piano si giunge al terzo anno, che inizia con il prevedibile fervore di noi fagioli per l'arrivo delle nuove matricole. Principalmente il mio interesse è rivolto a torturare le matricole con quesiti impossibili di analisi matematica, ma la situazione cambia decisamente quando, in preda ad un attacco di socializzazione acuta conosco Francesca (non quella di Nino). Le circostanze del nostro primo vero incontro sono decisamente imbarazzanti. La sua cecità la spinge alla cleptomania nei confronti dei miei occhiali, alla quale io reagisco insultando la sua terribile facoltà. Dopo nove mesi insieme, lei ancora mi ruba gli occhiali e io ancora la insulto perchè fa Chimica.

Reincontriamo di nuovo il Dappia, che tiene per la prima volta a noi un corso al terzo anno. Come se non bastasse, ce lo ritroviamo in un corso Iuss e persino in birreria al sabato sera. A questo punto pensiamo al complotto.

Procede tutto bene fino al momento in cui scopro che Nino mi ha battuto sul tempo: ha già chiesto lui la tesi al Dappia. Maledetto. Di reazione, la chiedo anche io al Dappia, che mi affida ad uno dei suoi scagnozzi Nicolò. Al ch , Nino decide di svendersi agli sperimentali, prima rimanendo invischiato in una tesi sperimentale sull'inutile massa del bosone chicchessia e poi spostandosi sulla fenomenologia della forza debole. Perch  Nino   un debole. Fattosta che a fine maggio mi rimangono ancora cinque esami da dare (eh s , quello con la Rimoldi per me   valso doppio) e della tesi ho scritto a malapena il primo capitolo. Ma l'importante, a questo punto,   salvare la faccia. Tutti i miei compagni se ne vanno verso altri, floridi, lidi e io manco sono capace di laurearmi a luglio. All'alba del 20 giugno, con ancora un esame da 12 crediti da dare e a sole tre settimane dalla consegna della tesi, decido di fare la follia. Chiss  quante maledizioni mi hanno tirato il Dappia e Nicol  quel giorno. Ma

se sono qui ora, vuol dire che ce l'ho fatta.

Più che ringraziamenti, ho molte scuse da fare. Mi scuso per aver trascurato in questi ultimi tempi tante persone che si meritavano molto di più da parte mia. Ho trascurato la mia famiglia, non tornando a casa quasi mai. Ho trascurato molti di quegli amici che ho citato prima. Ho trascurato la mia salute, mentale e fisica.

Ora è tutto finito, ma se pensate che mi dedicherò a voi fin da subito, vi sbagliate di grosso. Ora ho solo voglia di andare al mare. Ci vediamo a settembre, *bitches*!
